The value of the `layerObject.background` property is an image object (see Chapter 22). To change the image in that property on the fly, you must set the `layerObject.background.src` property to the URL of the desired image (just like changing `document.imageName.src` on the fly). You can remove the background image by setting the `layerObject.background.src` property to `null`. Background images smaller than the rectangle of the layer repeat themselves, just like document background pictures; images larger than the rectangle clip themselves to the rectangle of the layer rather than scaling to fit.

The IE4+ and NN6+ way of handling background images is through the `style.backgroundImage` property.

Example (with Listing 31-2) on the CD-ROM

Related Items: `layer.bgColor` property; image object.

bgColor

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

A layer's background color fills the entire rectangle with the color set in the `<LAYER>` tag or from a script at a later time. Color values are the same as for document-related values; they may be in the hexadecimal triplet format or in one of the plain-language color names. You can turn a layer transparent by setting its `bgColor` property to `null`.

You control the corresponding behavior in IE4+ and NN6+ via the `style.backgroundColor` property.

Example (with Listing 31-3) on the CD-ROM

Related Items: `layer.background` property; `layer.onMouseOver` event handler.

clip

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

The `layerObject.clip` property is an object (the only one in NN4's document object model that exposes itself as a rectangle object) with six geographical properties defining the position and size of a rectangular area of a layer visible to the user. Those six properties are

- ♦ `clip.top`
- ♦ `clip.left`
- ♦ `clip.bottom`
- ♦ `clip.right`
- ♦ `clip.width`
- ♦ `clip.height`

The unit of measure is pixels, and the values are relative to the top-left corner of the layer object.

A clip region can be the same size as or smaller than the layer object. If the `CLIP` attribute is not defined in the `<LAYER>` tag, the clipping region is the same size as the layer. In this case, the `clip.left` and `clip.top` values are automatically zero because the clip region starts at the very top-left corner of the layer's rectangle (measurement is relative to the layer object whose `clip` property you're dealing with). The height and width of the layer object are not available properties in NN4. Therefore, you may have to use other means to get that information into your scripts if you need it. (I do it in Listing 31-4.) Also be aware that even if you set the `HEIGHT` and `WIDTH` attributes of a layer tag, the content rules the initial size of the visible layer unless the tag also includes specific clipping instructions. Images, for example, expand a layer to fit the `HEIGHT` and `WIDTH` attributes of the `` tag; text (either from an external HTML file or inline in the current file) adheres to the `<LAYER>` tag's `WIDTH` attribute but flows down as far as necessary to display every character.

Setting a `clip` property does not move the layer or the content of the layer — only the visible area of the layer. Each adjustment has a unique impact on the apparent motion of the visible region. For example, if you increase the `clip.left` value from its original position of 0 to 20, the entire left edge of the rectangle shifts to the right by 20 pixels. No other edge moves. Changes to the `clip.width` property affect only the right edge; changes to the `clip.height` property affect only the bottom edge. Unfortunately, no shortcuts exist to adjust multiple edges at once. JavaScript is fast enough on most client machines to give the impression that multiple sides are moving if you issue assignment statements to different edges in sequence.

IE4+ and NN6+ have the `style.clip` property to assist in adjusting the clipping rectangle of a layer. But the W3C DOM's `style.clip` object does not offer additional subproperties to access individual edges or dimensions of the clipping

rectangle. IE5's read-only `currentStyle` object does provide properties for the four edge dimensions. Listing 31-15 demonstrates how to adjust clipping in IE5+ and NN6+ syntax.

Example (with Listing 31-4) on the CD-ROM

Related Items: `layer.pageX`, `layer.pageY` properties; `layer.resizeTo()` method.

document

Value: document object

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

Your scripts practically never have to retrieve the `document` property of a layer. But it is important to remember that it is always there as the actual container of content in the layer. As described at length in the opening section about the layer object, the `document` object reference plays a large role in assembling addresses to content items and properties in other layers. A document inside a layer has the same powers, properties, and methods of the main document in the browser window or in a frame.

Related Items: document object.

left top

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

The `layerObject.left` and `layerObject.top` properties correspond to the `LEFT` and `TOP` attributes of the `<LAYER>` tag. These integer values determine the horizontal and vertical pixel coordinate point of the top-left corner of the layer relative to the browser window, frame, or parent layer in which it lives. The coordinate system of the layer's most immediate container is the one that these properties reflect.

Adjustments to these properties reposition the layer without adjusting its size. Clipping area values are untouched by changes in these properties. Thus, if you create a draggable layer object that needs to follow a dragged mouse pointer in a

straight line along the x or y axis, it is more convenient to adjust one of these properties than to use the `layerObject.moveTo()` method.

IE4+ and NN6+ provide various properties to determine the coordinate location of a positioned element — all through the `style` object.

Example (with Listing 31-5) on the CD-ROM

Related Items: `layer.clip`, `layer.parentLayer` properties.

name

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

The `layerObject.name` property reflects the `NAME` attribute of the `<LAYER>` tag or name you assign to a positioned `DIV` or `SPAN` element. This property is read-only. If you don't assign a name to a layer when you create it, Navigator generates a name for the layer in this format:

```
js_layer_nn
```

Here, `nn` is a serial number. That serial number is not the same every time the page loads, so you cannot rely on the automatically generated name to help you script an absolute reference to the layer.

Related Items: None.

pageX

pageY

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

In Netscape's coordinate terminology, the *page* is the content area of a document. The top-left corner of the page space is point 0,0, and you can position any layer (including a nested layer) on the page relative to this corner. In the `<LAYER>` tag, the attributes that enable authors to set the position are `PAGEX` and `PAGEY`. These values are retrievable and modifiable as the `layerObject.pageX` and `layerObject.pageY` properties, respectively. Note the capitalization of the final letters of these property names.

The `layerObject.pageX` and `layerObject.pageY` values are identical to `layerObject.left` and `layerObject.top` only when the layer in question is at the main document level. That's because the `layerObject.left` and `layerObject.top` values are measured by the next higher container's coordinate system — which, in this case, is the same as the page.

The situation gets more interesting when you're dealing with nested layers. For a nested layer, the `layerObject.pageX` and `layerObject.pageY` values are still measured relative to the page, while `layerObject.left` and `layerObject.top` are measured relative to the next higher layer. If trying to conceive of these differences makes your head hurt, the example in Listing 31-6 should help clear things up for you.

Adjusting the `layerObject.pageX` and `layerObject.pageY` values of any layer has the same effect as using the `layerObject.moveToAbsolute()` method, which measures its coordinate system based on the page. If you create flying layers on your page, you can't go wrong by setting the `layerObject.pageX` and `layerObject.pageY` properties (or using the `moveToAbsolute()` method) in your script. That way, should you add another layer in the hierarchy between the base document and the flying layer, the animation is in the same coordinate system as before the new layer was added.

IE4+ does not provide a pair of properties to determine the location of a positioned element relative to the page, but the `offsetLeft` and `offsetTop` properties provide coordinates within the element's next outermost positioning context. Thus, you may have to “walk” the `offsetParent` trail to accumulate complete coordinate values. In NN6, the `offsetLeft` and `offsetTop` properties use the page as the positioning context.

Example (with Listing 31-6) on the CD-ROM

Related Items: `layer.left`, `layer.top`, `window.innerHeight`, `window.innerWidth` properties; `layer.moveToAbsolute()` method.

parentLayer

Value: Object

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

Every layer has a parent that contains that layer. In the case of a layer defined at the main document level, its parent layer is the window or frame containing that document (the “page”). For this kind of layer, the `layerObject.parentLayer` property object is a window object. But for any nested layer contained by a layer, the `parentLayer` property is a layer object.

Be aware of the important distinction between `layerObject.parentLayer` and `layerObject.below`. As a parent layer can contain multiple layers in the next containment level, each of those layers' `parentLayer` properties evaluate to that same parent layer. But because each layer object is its own physical layer among the stack of layers on a page, the `layer.below` property in each layer points to a different object — the layer next lower in z-order.

Keeping the direction of things straight can get confusing. On the one hand, you have a layer's parent, which, by connotation, is higher up the hierarchical chain of layers. On the other hand, the order of physical layers is such that a parent more than likely has a lower z-order than its children because it is defined earlier in the document.

Use the `layerObject.parentLayer` property to assemble references to other nested layers. See the discussion about layer references at the beginning of this chapter for several syntax examples.

IE4+ offers an `offsetParent` property, which comes close to the functionality of the `layerObject.parentLayer` property.

Related Items: `layer.above`, `layer.below` properties.

siblingAbove siblingBelow

See `layer.above` and `layer.below` properties earlier in this chapter.

src

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

Content for a layer may come from within the document that defines the layer or from an external source, such as an HTML or image file. If defined by a `<LAYER>` tag, an external file is specified by the `SRC` attribute. This attribute is reflected by the `layerObject.src` property.

The value of this property is a string of the URL of the external file. If you do not specify an `SRC` attribute in the `<LAYER>` tag, the value returns `null`. Do not set this property to an empty string in an effort to clear the layer of content: `document.write()` or load an empty page instead. Otherwise, the empty string is treated like a URL, and it loads the current client directory.

You can, however, change the content of a layer by loading a new source file into the layer. Simply assign a new URL to the `layerObject.src` property. Again, if a layer has nested layers inside it, those nested layers are blown away by the content that loads into the layer whose `src` property you change. The new file, of course, can be an HTML file that defines its own nested layers, which then become part of the page's object model.

Netscape also provides the `layerObject.load()` method to insert new content into a layer. One advantage of this method is that an optional second parameter enables you to redefine the width of the layer at the same time you specify a new document. But if you are simply replacing the content in the same width layer, you can use either way of loading new content.

Be aware that the height and width of a replacement layer are governed as much by their hard-coded content size as by the initial loading of any layer. For example, if your layer is initially sized at a width of 200 pixels and your replacement layer document includes an image whose width is set to 500 pixels, the layer expands its width to accommodate the larger content—unless you also restrict the view of the layer via the `layerObject.clip` properties. Similarly, longer text content flows beyond the bottom of the previously sized layer unless restricted by clipping properties.

Positioned elements in IE4+ and NN6+ do provide a way to load external content into them. That's what the W3C sees as the purpose of the IFRAME element. Even so, as Listing 31-18 shows, you can script your way around this limitation if it's absolutely necessary.

Example (with Listing 31-7) on the CD-ROM

Related Items: `layer.load()`, `layer.resizeTo()` methods.

visibility

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

A layer's `visibility` property can use one of three settings: `show`, `hide`, or `inherit`—the same values you can assign to the `VISIBILITY` attribute of the `<LAYER>` tag. But NN4 also enables you to set the property to `hidden` and `visible`, which are the values for the `style.visibility` property used in IE4+ and NN6+.

Unlike many other layer properties, you can set the `visibility` property such that a layer can either follow the behavior of its parent or strike out on its own. By default, a layer's `visibility` property is set to `inherit`, which means the layer's visibility is governed solely by that of its parent (and of *its* parent, if the nesting includes many layers). When the governing parent's property is, say, `hide`, the child's property remains `inherit`. Thus, you cannot tell whether an inheriting layer is presently visible or not without checking up the hierarchy (with the help of the `layerObject.parentLayer` property). However, you can override the parent's behavior by setting the current layer's property explicitly to `show` or `hide`. This action does not alter in any way other parent-child relationships between layers.

Example (with Listing 31-8) on the CD-ROM

Related Items: None.

zIndex

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

Close relationships exist among the `layerObject.above`, `layerObject.below`, and `layerObject.zIndex` properties. When you define a layer in a document with the `<LAYER>` tag, you can supply only one of the three attributes (`ABOVE`, `BELOW`, and `Z-INDEX`). After the layer is generated with any one of those attributes, the document object model automatically assigns values to at least two of those properties (`layerObject.above` and `layerObject.below`) unless you specify the `Z-INDEX` attribute; in this case, all three properties are assigned to the layer. If you don't specify any of these properties, the physical stacking order of the layers is the same as in the HTML document. The `layerObject.above` and `layerObject.below` properties are set as described in their discussion earlier in this chapter. But the `layerObject.zIndex` properties for all layers are zero.

The CSS attribute is spelled with a hyphen after the "z." Because a JavaScript property name cannot contain a hyphen, the character was removed for the property name. The capital "I" is important because JavaScript properties are case-sensitive.

Changes to `layerObject.zIndex` values affect the stacking order only of sibling layers. You can assign the same value to two layers, but the last layer to have its `layerObject.zIndex` property set lies physically above the other one. Therefore, if you want to ensure a stacking order, set the `zIndex` values for all layers within a container. Each value should be a unique number.

Stacking order is determined simply by the value of the integer assigned to the property. If you want to stack three sibling layers, the order is the same if you assign them the values of 1, 2, 3 or 10, 13, 50. As you modify a `layerObject.zIndex` value, the `layerObject.above` and `layerObject.below` properties for all affected layers change as a result.

Avoid setting `zIndex` property values to negative numbers in NN4. Negative values are treated as their absolute (positive) values for ordering.

For IE4+ and NN6+, the `style.zIndex` property controls z-order.

Example (with Listing 31-9) on the CD-ROM

Related Items: `layer.above`, `layer.below` properties; `layer.moveAbove()`, `layer.moveBelow()` methods.

Methods

`load("URL", newLayerWidth)`

Returns: Nothing.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

One way to change the content of an NN4 layer after it loads is to use the `layerObject.load()` method. This method has an advantage over setting the `layerObject.src` property because the second parameter is a new layer width for the content if one is desired. If you don't specify the second parameter, a small default value is substituted for you (unless the new document hard-wires widths to its elements that must expand the current width). If you are concerned about a new document being too long for the existing height of the layer, use the `layerObject.resizeTo()` method or set the individual `layerObject.clip` properties before loading the new document. This keeps the viewable area of the layer at a fixed size.

IE4+ and NN6 object models don't have a method like this, but you can work around the situation (as shown in Listing 31-18) and then adjust the `style.width` property of the positioned element.

Example (with Listing 31-10) on the CD-ROM

Related Item: `layer.src` property.

`moveAbove(layerObject)`
`moveBelow(layerObject)`

Returns: Nothing.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

With the exception of the `layerObject.zIndex` property, the layer object does not let you adjust properties that affect the global stacking order of layers. The `layerObject.moveAbove()` and `layerObject.moveBelow()` methods enable you to adjust a layer in relation to another layer object. Both layers in the transaction must be siblings — they must be in the same container, whether it be the base document window or some other layer. You cannot move existing layers from one

container to another; you must delete the layer from the source and create a new layer in the destination. Neither of these methods affects the viewable size or coordinate system location of the layer.

The syntax for these methods is a little strange at first because the statement that makes these work has two layer object references in it. Named first in the statement (to the left of the method name, separated by a period) is the layer object you want to move. The sole parameter for each method is a reference to the layer object that is the physical reference point for the trip. For example, in this statement,

```
document.fred.moveAbove(document.ginger)
```

the instruction moves the `fred` layer above the `ginger` layer. The `fred` layer can be in any stacking relation to `ginger`; but, again, both layers must be in the same container.

Obviously, after one of these moves, the `layerObject.above` and `layerObject.below` properties of some or all layers in the container feel the ripple effects of the shift in order. If you have several layers that are out of order because of user interaction with your scripts, you can reorder them using these methods — or, more practically, by setting their `layerObject.zIndex` properties. In the latter case, it is easier to visualize through your code how the ordering is handled with increasing `zIndex` values for each layer.

There is no comparable method for IE4+ or NN6.

Example on the CD-ROM

Related Items: `layer.above`, `layer.below`, `layer.zIndex` properties.

```
moveBy(deltaX,deltaY)
moveTo(x,y)
moveToAbsolute(x,y)
```

Returns: Nothing.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

Much of what CSS-Positioning is all about is being able to precisely plant an element on a Web page. The unit of measure is the pixel, with the coordinate space starting at an upper-left corner at location 0,0. That coordinate space for a layer is typically the container (parent layer) for that layer. The `layerObject.moveTo()` and `layerObject.moveBy()` methods let scripts adjust the location of a layer inside that coordinate space — very much the way `window.moveTo()` and `window.moveBy()` work for window objects.

Moving a layer entails moving it (and its nested layers) without adjusting its size or stacking order. You can accomplish animation of a layer by issuing a series of `layerObject.moveTo()` methods if you know the precise points along the path. Or you can nudge the layer by increments in one or both axes with the `layerObject.moveBy()` method.

In case you need to position a layer with respect to the page's coordinate system (for example, you are moving items from multiple containers to a common point), the `layerObject.moveToAbsolute()` method bypasses the layer's immediate container. The 0,0 point for this method is the top-left corner of the document. Be aware, however, that you can move a layer to a position such that some or all of it lies out of range of the container's clip rectangle.

Moving positioned layers in IE4+ and NN6 requires adjusting the `style.left` and `style.top` properties (or the `style.pixelLeft`, `style.pixelTop`, `style.posLeft`, and `style.posTop` properties in IE4+).

Example (with Listing 31-11) on the CD-ROM

Related Items: `layer.resizeBy()`, `layer.resizeTo()`, `window.moveBy()`, `window.moveTo()` methods.

`resizeBy(deltaX, deltaY)`
`resizeTo(width, height)`

Returns: Nothing.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

The basic functionality and parameter requirements of the `layerObject.resizeBy()` and `layerObject.resizeTo()` methods are similar to the identically named methods of the `window` object. You should, however, be cognizant of some considerations unique to layers.

Unlike resizing a window, which causes all content to reflow to fit the new size, the layer sizing methods don't adjust the size of the layer. Instead, these methods control the size of the clipping region of the layer. Therefore, the content of the layer does not reflow automatically when you use these methods any more than it does when you change individual `layerObject.clip` values.

Another impact of this clipping region relationship deals with content that extends beyond the bounds of the layer. For example, if you provide `HEIGHT` and `WIDTH` attributes to a `<LAYER>` tag, content that requires more space to display itself than those attribute settings afford automatically expands the viewable area of the layer. To rein in such runaway content, you can set the `CLIP` attribute. But because the layer resize methods adjust the clipping rectangle, oversized content doesn't overflow the `<LAYER>` tag's height and width settings. This may be beneficial for you

or not, depending on your design intentions. Adjusting the size of a layer with either method affects only the position of the right and bottom edges of the layer. The top-left location of the layer does not move.

Neither IE4+ nor NN6 provides a similar method, but you can accomplish the same effects by adjusting the `style` properties of a positioned element.

Example (with Listings 31-12a and 31-12b) on the CD-ROM

Related Items: `layer.moveBy()`, `layer.moveTo()`, `window.resizeBy()`, `window.resizeTo()` methods.

Event handlers

`onBlur`
`onFocus`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

A user gets no visual cue when a layer receives focus. But a click on the clipping region of a layer triggers a `focus` event that can be handled with an `onFocus` event handler. Clicking anywhere on the page outside of that layer area fires a `blur` event. Changing the stacking order of sibling layers does not fire either event unless mouse activity occurs in one of the layers.

If your layer contains elements that have their own `focus` and `blur` events (such as text fields), those objects' event handlers still fire even if you also have the same event handlers defined for the layer. The layer's events fire after the text field's events.

Unlike comparable event handlers in windows, layer events for `blur` and `focus` do not have companion methods to bring a layer into focus or to blur it. However, if you use the `focus()` and/or `blur()` methods on applicable form elements in a layer, the layer's corresponding event handlers are triggered as a result.

Related Items: `textbox.blur()`, `textbox.focus()` methods.

`onLoad`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

Scripting layers can sometimes lead to instances of unfortunate sequences of loading. For example, if you want to set some layer object properties via a script (that is, not in the `<LAYER>` tag), you can do so only after the layer object exists in

the document object model. One way to make sure the object exists is to place the scripting in `<SCRIPT>` tags at the end of the document. Another way is to specify an `onLoad` event handler in the tag, as shown in Listing 31-12a.

Each time you load a document into the layer — either via the `SRC` attribute in the `<LAYER>` tag or by invoking the `layerObject.load()` method — the `onLoad` event handler runs. But also be aware that an interaction occurs between a layer's `onLoad` event handler and an `onLoad` event handler in the `<BODY>` tag of a document loaded into a layer. If the document body has an `onLoad` event handler, then the layer's `onLoad` event handler does not fire. You get one or the other, but not both.

Related Item: `window.onLoad` event handler.

onMouseOut onMouseOver

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

A layer knows when the cursor rolls into and out of its clipping region. Like several other objects in the document object model, the layer object has `onMouseOver` and `onMouseOut` event handlers that enable you to perform any number of actions in response to those user activities. Typically, a layer's `onMouseOver` event handler changes colors, hides, or shows pseudo-borders devised of colored layers behind the primary layer; sometimes, it even changes the text or image content. The statusbar is also available to plant plain-language legends about the purpose of the layer or offer other relevant help.

Both events occur only once per entrance to, and egress from, a layer's region by the cursor. If you want to script actions dependent upon the location of the cursor in the layer, you can use `layerObject.captureEvents()` to grab mouseMove and all types of mouse button events. This kind of event capture generates an event object (see Chapter 29) that includes information about the coordinate position of the cursor at the time of the event.

Related Items: `link.onMouseOut`, `link.onMouseOver`, `area.onMouseOut`, `area.onMouseOver` event handlers.

Positioned Elements in the Modern DOM

With the dwindling NN4 installed base, you can focus on applying “layer” techniques in browsers whose object models expose every element of an object and whose rendering engines automatically reflow content in response to changes. This section follows the sequence of examples in the discussion about NN4's layer object but shows you how to accomplish the same operations and learn the behavior of positioned elements in IE4+ and NN6+.

An important facet that these newer browsers have in common is the `style` property of every renderable element object. Most adjustments to the location,

layering, size, and visibility of positioned elements use the `style` object associated with each element. Cross-browser complications ensue, however, with some aspects of nested layers. Plus, there is the ever-present difference between the IE- and NN-class browsers with respect to the event objects — how to reference the event object and the names of its properties. Some of the examples that follow have more code in them than their corresponding NN4 layer version shown earlier in this chapter. Most of the additional code concerns itself with accommodating the different event object models.

One more point about the following examples: The syntax adopted for references to element objects uses the W3C DOM `document.getElementById()` method, which is supported in IE5+ and NN6. If you intend to apply any of the techniques in these examples to applications that run exclusively in an IE environment (and must be compatible with IE4), you can substitute the `document.all` referencing syntax. Conversely, you can employ the `document.all` equalization routine shown in Chapter 14 to let IE4+ and NN6 use `document.all` references.

Changing element backgrounds

Listing 31-13 demonstrates the syntax and behavior of setting background images via the `style.backgroundImage` property. Note the CSS-style syntax for the URL value assigned to the `style.backgroundImage` property. It's a good lesson to learn that most `style` properties are strings, and their values are in the same format as the values normally assigned in a style sheet definition.

Removing a background image requires setting the URL to `null`. Also, a background image overlays whatever color (if any) you assign to the element. If the background image has transparent regions, the background color shows through.

Listing 31-13: Setting Layer Backgrounds (W3C)

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function setBg(URL) {
    document.getElementById("bgExpo").style.backgroundImage = "url(" + URL + ")"
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Layer Backgrounds (W3C)</H1>
<HR>

well with the various backgrounds.</SPAN>
</DIV>
</BODY>
</HTML>

```

Listing 31-14 focuses on background color. A color palette is laid out as a series of rectangles. As the user rolls atop a color in the palette, the color is assigned to the background of the layer. Because of the regularity of the DIV elements generated for the palette, this example uses scripts to dynamically write them to the page as the page loads. This lets the `for` loop handle all the positioning math based on initial values set as global variables.

Perhaps of more interest here than the background color setting is the event handling. First of all, because the target browsers all employ event bubbling, the page lets a single event handler at the document level wait for `mouseover` events to bubble up to the document level. But because the `mouseover` event of every element on the page bubbles there, the event handler must filter the events and process only those on the palette elements.

The `setColor()` method begins by equalizing the IE4+ and NN6 event object models. If an object is assigned to the `evt` parameter variable, then that means the NN6 browser is processing the event; otherwise, it's IE4+ — meaning that the `window.event` object contains the event information. Whichever browser performs the processing, the event object is assigned to the `evt` variable. After verifying that a valid event triggered the function, the next step is to equalize the different, event-model-specific property names for the event's target element. For NN6, the property is `target`, while IE4+ uses `srcElement`. The final validation is to check the `className` property of the event's target element. Because all elements acting as palette colors share the same `CLASS` attribute, the `className` property is examined. If the value is `palette`, then the `mouseover` event has occurred on one of the colors. Now it's time to extract the target element's `style.backgroundColor` property and assign that color to the same property of the main positioned element.

Listing 31-14: Layer Background Colors (W3C)

Layer clipping

Working with clipping rectangles is a bit cumbersome using CSS syntax because the object model standard does not provide separate readouts or controls over individual edges of a clipping rectangle. IE5+ enables you to read individual edge dimensions via the `currentStyle` object (for example, `currentStyle.clipTop`), but these properties are read-only. NN6 has not connected all the pieces of W3C DOM Level 2 that expose individual edges of a clipping rectangle yet.

Based on these limitations, Listing 31-15 is implemented in a way that, for the sake of convenience, preserves the current clipping rectangle edge values as global variables. Any adjustments to individual edge values are first recorded in those variables (in the `setClip()` function), and then the `style.clip` property is assigned the long string of values in the required format (in the `adjustClip()` function). The `showValues()` function reads the variable values and displays updated values after making the necessary calculations for the width and height of the clipping rectangle.

As a demonstration of a “reveal” visual effect (which you can carry out more simply in IE4+/Windows via a transition filter), the `revealClip()` function establishes beginning clip values at the midpoints of the width and height of the layer. Then the `setInterval()` method loops through `stepClip()` until the clipping rectangle dimensions match those of the layer.

Listing 31-16 enables you to compare the results of adjusting a clipping rectangle versus the size of a positioned element. This example goes a bit further than the corresponding NN4 layer version (Listing 31-5) in that it enables you to adjust the dimensions of the entire layer (via the `style.left` and `style.right` properties) as well as the right and bottom edges of the clipping rectangle associated with the layer. As a bonus, the code includes a function that converts the `style.clip` string into an object representing the rectangle of the clipping rectangle (in other words, with four properties, one for each edge). Values from that `rectangle` object populate two of the fields on the page, providing dynamic readouts of the clipping rectangle's right and bottom edges.

Global variables still temporarily store the clipping rectangle values so that the `adjustClip()` function can operate just as it does in Listing 31-15. Note that the clipping rectangle is explicitly defined in the style sheet rule for the positioned element. This is necessary for the element's `style.clip` property to have some values with which to start.

Scripting nested layers

Working with nested layer locations, especially in a cross-browser manner, presents numerous browser-specific syntax problems that need equalization to behave the same to all users. Some discrepancies even appear between Windows and Macintosh versions of IE.

The scenario for Listing 31-17 consists of one positioned layer (greenish) nested inside another (reddish). The inner layer is initially sized and positioned so that the outer layer extends five pixels in each direction. Text boxes enable you to adjust the coordinates for either layer relative to the entire page as well as the layer's positioning context. If you make a change to any one value, all the others are recalculated and displayed to show you the effect the change has on other coordinate values.

As you see when you load the page, the outer element's positioning context is the page, so the "page" and "container" coordinates are the same (although the calculations to achieve this equality are not so simple across all browsers). The inner layer's initial page coordinates are to the right and down five pixels in each direction, and the coordinates within the container show those five pixels.

Because of browser idiosyncrasies, calculating the coordinates within the page takes the most work. The `getGrossOffsetLeft()` and `getGrossOffsetTop()` functions perform those calculations in the page. Passed a reference to the positioned element to be measured, the first number to grab is whatever the browser returns as the `offsetLeft` or `offsetTop` value of the element (see Chapter 15). These values are independent of the `style` property, and they can report different values for different browsers. IE, for example, measures the offset with respect to whatever it determines as the next outermost positioning context. NN6, on the other hand, treats the page as the positioning context regardless of nesting. So, as long as there is an `offsetParent` element, a `while` loop starts accumulating the `offsetLeft` measures of each succeeding offset parent element going outward from the element. But even before that happens, a correction for IE/Macintosh must be accounted for. If there is a difference between the `style.left` and `offsetLeft` property values of an element, that difference is added to the offset. In IE5/Mac, for example, failure to correct this results in the "page" and "container" values of the outer layer being 10 pixels different in each direction. Values returned from these two gross measures are inserted in the readouts for the "page" measures of both inner and outer elements.

Reading the coordinates relative to each element's "container" is easy: The `style.left` and `style.top` properties have the correct values for all browsers. Moving a layer with respect to its positioning context (the "container" values) is equally easy: assign the entered values to the same `style.left` and `style.top` properties.

Moving the layers with respect to the page coordinate planes (via the `setOuterPage()` and `setInnerPage()` functions) involves going the long way to assign values that take each browser's positioning idiosyncrasies into account. The way you move a positioned element (cross-browser, anyway) is to assign a value to the `style.left` and `style.top` properties. These values are relative to their positioning context, but NN6 doesn't offer any shortcuts to reveal what element is the positioning context for a nested element. Calls to the `getNetOffsetLeft()` and `getNetOffsetTop()` functions do the inverse of the `getGrossOffsetLeft()` and `getGrossOffsetTop()` functions. Because the values received from the text box are relative to the entire page, the values must have any intervening positioning contexts subtracted from that value in order to achieve the net positioning values that can be applied to the `style.left` and `style.top` properties. To get there, however, a call to the `getParentLayer()` function cuts through the browser-specific implementations of container references to locate the positioning context so that its coordinate values can be subtracted properly. The same kind of correction for IE/Mac is required here as in the gross offset calculations; but here, the correction is subtracted from the value that eventually is returned as the value for either the `style.left` or `style.top` of the layer.

Let me add one quick word about the condition statements of the `while` constructions in the `getNetOffsetLeft()` and `getNetOffsetTop()` functions. You see here a construction not used frequently in this book, but one that is perfectly legal. When the conditional expression evaluates, the `getParentLayer()` method is invoked, and its returned value is assigned to the `elem` variable. That expression evaluates to the value returned by the function. As you can see from the `getParentLayer()` function definition, a value is returned as either an element reference or `null`. The `while` condition treats a value of `null` as `false`; any reference to an object is treated as `true`. Thus, the conditional expression does not use a comparison operator but rather executes some code and branches based on the value returned by that code. NN6 reports JavaScript warnings (not errors) for this construction because it tries to alert you to a common scripting bug that occurs when you use the `=` operator when you really mean the `==` operator. But an NN6 warning is not the same as a script error, so don't be concerned when you see these messages in the JavaScript Console window during your debugging.

Try entering a variety of values in all text boxes to see what happens. Here is one possible sequence of tests and explanations:

1. Increase the red Page X value to 250. This moves the outer layer to the right by 50 pixels. Because the green layer is nested inside, it moves along with it. The green's Page X value also increases by 50, but its Container X value remains the same because the inner layer maintains the same relationship with the outer layer as before.
2. Increase the green Page X value to 300. This action shifts the position of the green inner layer by 45 pixels, making it a total of 50 pixels inset within its positioning context. Because the outer layer does not have its clipping rectangle set, the inner layer's content bleeds beyond the width of the red layer.
3. Set the Container Y value to -50. This action moves the green inner layer upward so that its top is 50 pixels above the top of its red container. As a result, the Page Y value of the inner layer is 80, while the Page Y value of the red outer layer remains at 130 (thus, the 50-pixel difference).

As you experiment with moving the layers around, you may encounter some screen refresh problems where traces of the inner layer remain when moved beyond the outer layer's rectangle. Take these bugs into account when you design the actions of your script-controlled positioning.

Loading external HTML into a layer

The NN4 layer object had an unfair advantage when it came to loading external content into it: the element was designed to do just that, acting in some ways like the W3C-endorsed IFRAME element.

Because the IE4+ and NN6 object models embrace the IFRAME element, using that element may be the easy way for you to designate a space within a page for external content. In fact, you can even assign a style sheet rule that absolute-positions the IFRAME precisely on the page where you want it. Be sure to set the `FRAMEBORDER` attribute to 0 unless you want the border to be visible to the user (and then watch out for content that may overrun the rectangle and cause scrollbars to appear). In this case, you must then leave all the formatting and style sheet control of that content to the HTML loaded into the IFRAME, just as if it were in a separate window or frame. To load different content into the element, assign a different URL to the `src` property of the IFRAME element object.

As one more example that more closely simulates the loading of external content into a layer, Listing 31-18 demonstrates a somewhat ugly workaround that lets a layer's background color or image show through some kinds of HTML content. The technique works only in IE5.5+ and NN6 because these browser generations are the first to offer scripted access to the HTML you need to load into an intermediate (and hidden) IFRAME before stuffing the content into the layer.

A hidden IFRAME element is the initial recipient of the external HTML file, as loaded by the `loadOuter()` method. When that file loads, the `transferHTML()` method is invoked to copy the `innerHTML` of just the BODY element of the content window of the IFRAME (note the different syntax for NN6—the `contentDocument` property—and IE5.5—the `contentWindow` property). By eliminating the BODY

element and any tags in the HEAD, you prevent the tags in the layer from conflicting with the tags for the main document. As a result, however, notice how the background color set for the layer shows through the HTML plugged into the layer.

HTML element objects (other than IFRAME) were not designed to get their content from external files. But, as Listing 31-18 shows, where there is a will there is a way—even if the workaround isn't pretty.

Listing 31-18: Setting Layer Source Content (W3C)

```
<HTML>

</DIV>
<IFRAME ID="hiddenContent" STYLE="visibility:hidden"
onLoad="transferHTML()"></IFRAME>
</BODY>
</HTML>
```

Positioned element visibility behavior

There is very little code in Listing 31-19 because it simply adjusts the `style.visibility` property of an outer layer and a nested, inner layer. You can see that when the page loads, the green inner layer's visibility is automatically set to inherit the visibility of its containing outer layer. When you click the outer layer buttons, the inner layer blindly follows the settings.

Things change, however, once you start adjusting the properties of the inner layer independently of the outer layer. With the outer layer hidden, you can show the inner layer. Only by setting the `visibility` property of the inner layer to `inherit` can you make it rejoin the outer layer in its behavior.

Listing 31-19: Nested Layer Visibility Relationships (W3C)

Scripting layer stacking order

Listing 31-20 is simpler than its NN4 layer-specific version (Listing 31-9) because the W3C DOM, as implemented in IE4+ and NN6, does not have properties that reveal the equivalent of the `layerObject.above` or `layerObject.below` properties. Therefore, Listing 31-20 confines itself to enabling you to adjust the `style.zIndex` property values of three overlapping layers. All three layers (none of which are nested inside another) initially set their `zIndex` values to 0, meaning that the source code order rules the stacking order.

If you try this example on both IE4+ and NN6, however, you will experience a significant difference in the behavior of overlapping layers in the two browser categories. For example, if you reload the page to let source code order lay out the layers initially, and then set the green middle layer to, say, 5, the middle layer plants itself in front of the other two in both browser categories. But if you restore the middle layer's `zIndex` value to 0, IE puts it back in source code order. NN6, on the other hand, leaves it in front of the other two. The rule of thumb (which also applies to NN4) is that if scripts modify the `zIndex` property of multiple layers to all the same value, the most recently set layer stays in front of the others.

There is some method to this seeming madness, which you can experience in Chapter 56's map puzzle game. If you drag one of several draggable elements around the page, you probably will set its `zIndex` to a value higher than that of all the others so that the currently active element stays in front of the rest. But when you complete the dragging, you will want to restore the `zIndex` to its original value, which may be the same as that of all the other draggable items. By keeping the most recently adjusted layer on top, you keep the layer you just dropped in front of the others in case you want to pick it up again.

Listing 31-20: Relationships Among `zIndex` Values (W3C)

Dragging and resizing a layer

Listing 31-21 is an IE4+- and NN6-compatible version of the layer dragging example shown earlier in Listing 31-11. The basic structure is the same, with event handler functions for engaging the drag mode, handling the mouse movement while in drag mode, and releasing the element at the end of the journey.

There is a lot more code in this version for several reasons. The main reason is to accommodate the two event object models in the IE and NN browsers. First of all, event bubbling is used so that all mouse events are handled at the document level. Thus, all of the event handlers need to equalize the `event` object and event target element, as well as filter events so that the action occurs only when a draggable element (as identified by its `className` property) is the target of the event action.

The toughest job involves the `engage()` function because it must use the two different event and element object models to establish the offset of the `mousedown` event within the draggable element. For IE/Windows, this also means taking the scrolling of the body into account. To get the element to reposition itself with mouse motion, the `dragIt()` function applies browser-specific coordinate values to the `style.left` and `style.top` properties of the draggable element. This function is invoked very frequently in response to the `mousemove` event.

One extra event handler in this version, `onmouseout`, disengages the drag action. This event occurs only if the user moves the cursor faster than the browser can update the position.

Nothing in this example, however, treats the `zIndex` stacking order, which must be addressed if the page contains multiple, draggable items. See the map puzzle game in Chapter 56 for an example of processing multiple, draggable items.

Listing 31-21: Dragging a Layer (W3C)

```

<HTML>
<HEAD>
<TITLE>Layer Dragging</TITLE>
<STYLE TYPE="text/css">

```

```

.draggable {cursor:hand}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
var engaged = false
var offsetX = 0
var offsetY = 0
function dragIt(evt) {
    evt = (evt) ? evt : (window.event) ? window.event : ""
    var targElem = (evt.target) ? evt.target : evt.srcElement
    if (engaged) {
        if (targElem.className == "draggable") {
            while (targElem.id != "myLayer" && targElem.parentNode) {
                targElem = targElem.parentNode
            }
            if (evt.pageX) {
                targElem.style.left = evt.pageX - offsetX + "px"
                targElem.style.top = evt.pageY - offsetY + "px"
            } else {
                targElem.style.left = evt.clientX - offsetX + "px"
                targElem.style.top = evt.clientY - offsetY + "px"
            }
            return false
        }
    }
}

        while (targElem.id != "myLayer" && targElem.parentNode) {
            targElem = targElem.parentNode
        }
        if (engaged && targElem.id == "myLayer") {
            engaged = false
        }
    }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Dragging a Layer</H1>
<HR>
<DIV ID="myLayer" CLASS="draggable" STYLE="position:absolute; top:90; left:100;
width:300; height:190; background-color:lightgreen">
    <SPAN CLASS="draggable"><B>Drag me around the window.</B></SPAN>
</LAYER>
<SCRIPT LANGUAGE="JavaScript">
document.onmousedown = engage
document.onmouseup = release
document.onmousemove = dragIt
document.onmouseout = release
</SCRIPT>
</BODY>
</HTML>

```

The final listing in this section applies many example components used thus far to let scripts control the resizing of a positionable element by dragging the lower-right, 20-pixel region. A lot of the hairy code in the `engage()` function is for determining if the `onmousedown` event occurs in the invisible 20-pixel square.

The `resizeIt()` function of Listing 31-22 resembles the `dragIt()` function of Listing 31-21, but the adjustments are made to the width and height of the positionable element. A fair amount of math determines the width of the element in response to the cursor's instantaneous location and sets the `style.width` and `style.height` properties accordingly.

A user's success with resizing an element this way depends a lot on the browser he or she uses. IE, particularly for Windows, may not redraw the resized element very quickly. In this case, the cursor can easily slip out of the hot spot to end the drag. In other browsers, however, response is very fast, and it's very difficult to have the `onmouseout` event fire the `release()` function.

Listing 31-22: Resizing a Layer (W3C)

```

<HTML>
<HEAD>
<TITLE>Layer Resizing</TITLE>
<SCRIPT LANGUAGE="JavaScript">

```

This chapter only scratches the surface in the kinds of positioned element actions you can control via scripts. You may have seen examples of positioned element scripting at sites around the Web. For example, some pages have subject headers fly into place—even “bounce” around until they settle into position. Or elements can go in circles or spirals to get your attention (or distract you, as the case may be). The authors of those tricks apply formulas from other disciplines (such as games programming) to the `style` object properties of a positioned element.

Sometimes the effects are there just for the sake of looking (at first anyway) cool or because the page author knows how to script those effects. Your chief guide in implementing such features, however, should be whether the scripting genuinely adds value to the content offering. If you don't improve the content by adding a flying doo-dad or pulsating images, then leave them out. A greater challenge is finding meaningful ways to apply positioning techniques. Done the right way and for the right reason, they can significantly enhance the visitor's enjoyment of your application.

Embedded Objects

In addition to the typical content that you see in Web pages — primarily text and images — you can embed other kinds of content into the page. Such embedded content usually requires the powers of additional software, such as plug-in players or other external code processors, to load and display the content. All of this external content is added to a page by one of three HTML elements: APPLET, EMBED, or OBJECT. In the HTML 4.0 standard, the APPLET element, which was intended originally for loading Java applets, is deprecated in favor of the newer OBJECT element. An OBJECT element is intended to be more extensible, meaning that it has enough attributes and power to summon the Java virtual machine if the incoming code is a Java applet, or run an ActiveX program (in IE for Windows, that is). The EMBED element is commonly used to display a plug-in control panel directly in the document, rather than having the panel appear in a separate window.

In all cases, when a visual element is embedded via any of these elements, the control panel or applet occupies a segregated rectangular space on the page and generally confines its activities to that rectangle. But in many cases, JavaScript can also interact with the content or the player, allowing your scripts to extend themselves with powers for actions, such as controlling audio playback or the operation of a Java applet.

This chapter's primary focus is not on the content and players that you can control as it is on the HTML element objects that load the content or players into the page in the first place. Most of the properties represent nothing more than scriptable access to the element HTML attributes. The property descriptions in this chapter are therefore not extensive. Online HTML references (including the W3C HTML 4.0 specification and the Microsoft Developer Network documentation) should fill in the attribute value information quite well. In practice, scripts have very little interaction with these element objects, but if you ever need to know what's scriptable, you'll find that information here. As for controlling applets and plug-ins, you can find information about that in Chapter 44.

(Applet variables)		

Syntax

Accessing APPLET element object properties or methods:

```
(NN3+/IE4+) [window.]document.appletName.property | method([parameters])
(NN3+/IE4+) [window.]document.applets[index].property | method([parameters])
(IE4+) [window.]document.all.appletID.property | method([parameters])
(IE5+/NN6) [window.]document.getElementById("appletID").property |
method([parameters])
```

About this object

Starting with NN3 and IE4, Java applets are treated as scriptable objects. While IE4+ treats both the applet and the APPLET element as objects, NN3 and NN4 offered access to only one property of the APPLET element object (name). In NN6, however, many more APPLET object properties are also scriptable.

The fact that the applet, itself, can expose public instance variables and public methods as properties and methods of the applet object means that the scriptable characteristics of an applet object are highly dependent upon the way the applet was written. You can learn more about how to compose an applet that exposes its innards to JavaScript in Chapter 44.

Perhaps the most important point to remember about accessing applets is that you must have them loaded and running before you can address them as objects.

Although you cannot query an applet to find out whether it's loaded (as you can with an image), you can rely on the `onLoad` event handler of a window to fire only when all applets in the window are loaded and running (with the occasional version- or platform-specific bug in frames, as described in the `window.onLoad` event handler discussion in Chapter 16). IE4+ also features an `onLoad` event handler for the `APPLET` element directly, but applets tend to be the last things to load on a page. Therefore, you won't be able to use an applet embedded in a document to help you create the HTML content of that page as it loads, but an applet can provide content for new documents or for modifiable elements of a page. With the highly dynamic object models of IE4+ and NN6, this can lead to all kinds of possibilities.

Java applets have also been used to maintain contact with a server after the page has loaded by way of a servlet running on the server. A servlet allows the applet to query or be refreshed with instantaneously updated information without having to reload the page. Of course, getting a sophisticated applet to run in a wide range of browsers and operating systems is a challenge unto itself.

A large set of event handlers for this element (all but `onLoad` and `onScroll`) is related to the application of IE/Windows data binding for `PARAM` elements nested inside an `APPLET` element. These events fire when a variety of actions occur to the data source or recordset associated with the applet. For more about applying data binding to an `APPLET` element, see <http://msdn.microsoft.com/workshop/author/databind/dataconsumer.asp>.

Properties

`align`

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `align` property controls either the horizontal or vertical alignment of the element with regard to surrounding content. String values of `left` or `right` cause the applet rectangle to cling to the left or right edges of its next outermost positioning context. String values of `absbottom`, `absmiddle`, `baseline`, `bottom`, `middle`, `text-top`, or `top` influence the vertical alignment with respect to adjacent text, with the same kind of results as corresponding values of the `style.verticalAlign` property.

Related Items: `style.verticalAlign` property.

`alt`

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

The `alt` property represents the ALT attribute, which should contain text that displays in the browser in the event that the applet does not load or the user has Java turned off in the browser preferences. This information should be set as the APPLET element's attribute, because assigning text to the property after the applet attempts to load does not insert the text into the page.

Related Items: `altHTML` property.

`altHTML`

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `altHTML` property is supposed to provide an APPLET element with HTML content to render if the applet doesn't load. In practice, assigning an HTML string to this property has no effect on an APPLET element.

Related Items: `alt` property.

`archive`

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility					✓				

The `archive` property represents the ARCHIVE attribute, which points to the URL of a compressed (.zip) file containing Java class files needed for the applet. The archive must include the class file that is assigned to the CODE attribute to get the applet loaded and started.

Related Items: `code` property.

`code`

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `code` property is the URL string of the Java class file that is to begin loading the applet (or the property may be the entire applet if it consists of a single class

file). You cannot change the code assigned to an applet after the element has loaded (even if the applet code did not load successfully).

Related Items: `codeBase` property.

codeBase

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `codeBase` property is the string of the path on the server to the Java class file that is to begin loading the applet (or the property may be the entire applet if it consists of a single class file). The actual Java class file name is not part of the `codeBase` property.

Related Items: `code` property.

height width

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `height` and `width` properties represent the `HEIGHT` and `WIDTH` attributes of the `APPLET` element. While these values should be set via attributes in the tag, these properties can adjust the size of the applet after the fact in IE5+.

Related Items: `hspace`, `vspace` properties.

hspace vspace

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `hspace` and `vspace` properties represent the `HSPACE` and `VSPACE` attributes of the `APPLET` element, which control the number of pixels of transparent padding around the `APPLET` element on the page. While these values should be set via

attributes in the tag, these properties can adjust the size of the applet padding after the fact in IE5+.

Related Items: `height`, `width` properties.

name

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `name` property represents the `NAME` attribute, a holdover from the early implementations of the `APPLET` element before `ID` attributes were used to identify elements. The value assigned to the `NAME` attribute is the name you can use to reference applets in all browsers that support accessing applets:

`document.appletName`.

object

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

The `object` property represents the `OBJECT` attribute, which, according to the W3C HTML standard, points to the URL of a serialized (that is, “saved”) version of the applet’s current state. This attribute, and thus the associated property, may not be fully implemented in NN6.

Related Items: `code` property.

vspace

See `hspace`.

width

See `height`.

OBJECT Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

*See Text.

Syntax

Accessing OBJECT element object properties or methods:

```
(IE4+) [window.]document.all.objectID.property | method([parameters])
(IE5+/NN6) [window.]document.getElementById("objectID").property |
method([parameters])
```

About this object

The OBJECT element is intended to be the primary way to add external content (that is, content that the browser itself does not render) to a page. For example, IE/Windows uses it to load ActiveX controls (whether from the server or locally). The OBJECT element is also destined to replace usage of the APPLET and EMBED elements.

As with the APPLET element object, scripts can frequently control the programs and plug-ins that get loaded into the browser through the OBJECT tag. Chapter 44 shows you how to do that for common objects. The property listings here are merely for the properties of the element, most of which mimic the attributes available for the OBJECT element. Even though the properties are exposed, they are very rarely scripted, except perhaps to adjust the size of the space occupied by a media controller. Most properties are read-only after their values are set by attributes in the element's tag. But if your scripts are creating the OBJECT element anew, then scripts can set the property values the first time to initialize the object.

In the list of properties that begins this object's coverage, several are marked with an asterisk (*). These properties are defined in the W3C DOM Level 2 specification, and placeholders are included in the NN6 code. But as of this writing, there is no indication that these properties are "connected."

A large set of event handlers for this element (all but `onLoad` and `onScroll`) is related to the application of IE/Windows data binding for PARAM elements nested inside an OBJECT element. These events fire when a variety of actions occur to the data source or recordset associated with the program associated with the element. For more about applying data binding to an OBJECT element, see <http://msdn.microsoft.com/workshop/author/databind/dataconsumer.asp>.

Properties

align

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `align` property controls either the horizontal or vertical alignment of the element with regard to surrounding content. String values of `left` or `right` cause the object rectangle to cling to the left or right edges of its next outermost positioning context. String values of `absbottom`, `absmiddle`, `baseline`, `bottom`, `middle`, `texttop`, or `top` influence the vertical alignment with respect to adjacent text, with the same kind of results as corresponding values of the `style.verticalAlign` property.

Related Items: `style.verticalAlign` property.

alt

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

The `alt` property represents the ALT attribute, which should contain text that displays in the browser in the event that the object or its data do not load. This information should be set as the OBJECT element's attribute, because assigning text to the property after the object attempts to load does not insert the text into the page.

Related Items: `altHTML` property.

altHTML

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `altHTML` property is supposed to provide an OBJECT element with HTML content to render if the object doesn't load. In practice, assigning an HTML string to this property has no effect on an OBJECT element.

Related Items: `alt` property.

BaseHref

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `BaseHref` property returns the full URL path to the current document.

Related Items: None.

classid

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `classid` property represents the `CLASSID` attribute of the `OBJECT` element. IE for Windows uses this attribute to assign the Globally Unique ID (GUID) of an ActiveX control. For example, to load a (nearly) invisible Windows Media Player object into a page, the HTML is as follows:

```
<OBJECT ID="medPlayer" WIDTH="1" HEIGHT="1"
CLASSID="CLSID:22d6f312-b0f6-11d0-94ab-0080c74c7e95"
CODEBASE="#Version=1,0,0,0">
```

If your script then accesses the `classid` property of the `medPlayer` object, the value returned is the complete string as assigned to the attribute:
`CLSID:22d6f312-b0f6-11d0-94ab-0080c74c7e95`

Note that the `CLSID:` prefix is also part of the string value. Even if the object does not load (for example, because the object is missing or an error is in the long `CLASSID` string), the property value reports the value as assigned to the attribute.

The HTML 4.0 specification indicates that the `CLASSID` attribute be used for any kind of external class files, including Java applets. But in practice, IE wants applet URLs supplied to the `CODE` attribute (a non-HTML 4.0 attribute).

Related Items: `code` property.

code

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `code` property is the URL string of a Java class file that is to begin loading the applet (or the property may be the entire applet if it consists of a single class file). You cannot change the code assigned to an applet after the element has loaded (even if the applet code did not load successfully).

Related Items: `codeBase` property.

codeBase

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `codeBase` property is the string of the path on the server to the source of the applet or ActiveX control referenced by the `CLASSID` or `CODE` attributes. IE4+ also uses the `CODEBASE` attribute to specify a minimum version of control that is to

load, if the attribute is available. This facet is discussed in Chapter 28's coverage of plug-in detection for IE/Windows.

Related Items: code property.

codeType

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `codeType` property is a string of the MIME type of whatever object is pointed to by the `CODE` attribute value.

Related Items: type property.

height width

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `height` and `width` properties represent the `HEIGHT` and `WIDTH` attributes of the `OBJECT` element. While these values should be set via attributes in the tag, these properties can adjust the size of the embedded element after the fact in IE5+.

Related Items: `hspace`, `vspace` properties.

hspace vspace

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `hspace` and `vspace` properties represent the `HSPACE` and `VSPACE` attributes of the `OBJECT` element, which control the number of pixels of transparent padding around the `OBJECT` element on the page. While these values should be set via

attributes in the tag, these properties can adjust the size of the padding around the element after the fact in IE5+.

Related Items: height, width properties.

name

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `name` property represents the `NAME` attribute of the `OBJECT` element. The better form is to assign an ID to the `OBJECT` element and use accepted reference syntax for element ids.

Related Items: None.

object

Value: External Object

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `object` property returns a reference to the object contained by the `OBJECT` element. This property is essential if the program running inside the `OBJECT` element has the same property or method names as the `OBJECT` element itself. For example, consider a Java applet loaded into the `OBJECT` element as follows:

```
<OBJECT CODE="coolApplet" ID="myAPPLET" ... >
```

If the applet code contained a public variable called `height`, an attempt to read or write that property through the `OBJECT` element will cause the element's properties to be read, and not the applet's properties. Therefore, if you insert the `object` property in the reference, the script reaches into the applet object for the property:

```
document.getElementById("myAPPLET").object.height = 40
```

If there is no ambiguity between element and object property and method names, the browser looks first at the element and then the object to find a match.

Related Items: None.

type

Value: String Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `type` property represents the `TYPE` attribute of the `OBJECT` element, which, in theory anyway, is intended to warn the browser about the MIME type of data that is to be loaded into the object's process. I say "in theory" because the HTML 4.0 specification links the `TYPE` attribute to the `DATA` attribute, which points to the data to be loaded to support whatever program code is loaded via the `CLASSID` or `CODE` attribute. But through IE5.5, there is no support for the `DATA` attribute.

Related Items: `codeType` property.

vspace

See `hspace`.

width

See `height`.

EMBED Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>align</code>	(Object methods)	<code>onLoad</code>
<code>height</code>		<code>onScroll</code>
<code>hidden</code>		
<code>name</code>		
<code>pluginspage</code>		
<code>src</code>		
<code>units</code>		
<code>width</code>		
(Object variables)		

Syntax

Accessing EMBED element object properties or methods:

```
(IE4+)      [window.]document.all.objectID.property | method([parameters])
(IE5+/NN6) [window.]document.getElementById("objectID").property |
           method([parameters])
```

About this object

An EMBED element is a carryover from the early browser days. Although never adopted by the W3C HTML standard, the EMBED element has been used in NN and IE as a way to embed non-native content (for example, sounds, video clips, and custom MIME types for plug-ins, such as Shockwave) into a page. What gets embedded into the page is the controller or viewer for whatever kind of data the EMBED element points to (via the SRC attribute).

The EMBED element is far less sophisticated than the OBJECT element, but current browsers continue to support it. If you have been using the EMBED element in previous applications, it may be a good idea to start gravitating toward the OBJECT element. For backward compatibility purposes, nesting an EMBED element inside an OBJECT element is not uncommon, both of which attempt to load the same content and plug-in. Browsers that know about the OBJECT element will load the content that way; older browsers will use the EMBED element and its attributes and parameters.

Because an EMBED element loads a plug-in (including ActiveX control types of plug-ins in IE/Windows), you can reference the plug-in's properties and methods through the EMBED object's reference.

Properties

align

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The align property controls either the horizontal or vertical alignment of the element with regard to surrounding content. String values of left or right cause the object rectangle to cling to the left or right edges of its next outermost positioning context. String values of absbottom, absmiddle, baseline, bottom, middle, texttop, or top influence the vertical alignment with respect to adjacent text, with the same kind of results as corresponding values of the style.verticalAlign property.

Related Items: style.verticalAlign property.

height width

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `height` and `width` properties represent the `HEIGHT` and `WIDTH` attributes of the `EMBED` element. While these values should be set via attributes in the tag, these properties can adjust the size of the element after the fact in IE5+.

Related Items: None.

hidden

Value: Boolean

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `hidden` property represents the `HIDDEN` attribute of the `EMBED` element. When an `EMBED` element is hidden, neither controller nor the content is shown. Application of this element in modern browsers should use style sheets to hide and show the element.

Related Items: `style.visibility` property.

name

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `name` property represents the `NAME` attribute of the `EMBED` element. The better form is to assign an ID to the `EMBED` element and use accepted reference syntax for element ids.

Related Items: None.

pluginspage

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `pluginspage` property represents the `PLUGINSPAGE` attribute of the `EMBED` element. This attribute is a URL that gets applied to a link in the browser if the plug-in associated with the external file's MIME type cannot be found on the client.

Related Items: None.

src

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

The `src` property represents the `SRC` attribute of the `EMBED` element. This attribute points to the external file that is to be loaded into the browser via the associated plug-in. Scripts can assign a new URL string to this property to load a different file into the current plug-in.

Related Items: None.

units

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

The `units` property returns the unit of measure assigned with the length value of the `height` and `width` properties. In IE4, this property returned only `px`. The property does not appear to be connected in IE5.5, so it is probably deprecated in IE.

Related Items: `height`, `width` properties.

The Odd Case of the PARAM Element

HTML pages pass parameters to Java applets, plug-ins, and ActiveX controls by way of PARAM elements that are nested inside APPLET, EMBED, and OBJECT elements. Although a PARAM element object is defined by the W3C DOM Level 2 specification, it does not show up on some browsers' radar when you try to reference the PARAM element by itself. Even assigning an ID to a PARAM element or using `document.getElementsByTagName("PARAM")` fail to allow references to access an individual PARAM element object. At most, you can retrieve the `innerHTML` property of the surrounding element. But even here, the values returned may not necessarily be precisely the HTML you specify in the document.

In practice, this limitation is not particularly important. For one thing, even if you could access the PARAM elements of an embedded object or program, attempts to modify the values would be wasted: Those values are read at load time only. Secondly, a well-designed plug-in, applet, or ActiveX control will provide its own properties or methods to retrieve the current settings of whatever properties are initialized via the PARAM elements.

XML Objects

XML (eXtensible Markup Language) is an undeniably hot topic in the Internet world. Not only has the W3C organization formed multiple working groups and recommendations for XML and its offshoots, but the W3C DOM recommendation also has XML in mind when it comes to defining how elements, attributes, and data of any kind — not just the HTML vocabulary — are exposed to browsers as an object model. Most of the arcana of the W3C DOM Core specification — especially the structure based on the node — are in direct response to the XML possibilities of documents that are beginning to travel the Internet.

While XML documents can stand alone as containers of structured data in both IE5+ and NN6, the Windows version of IE5+ permits XML data to be embedded as “islands” in an HTML document. Such islands are encased in an XML element — an IE-specific extension of HTML.

It’s important to distinguish between “the” XML element — the element generated in a document by the IE-specific `<XML>` tag set — and a generic XML element that is a part of the XML data island. Generic XML elements have tag names that are meaningful to a data application, and they are usually defined by a separate Document Type Declaration (DTD) that contains a formal specification of the element names, their attributes (if any) and the nature of the data they can contain. Out of necessity, this book assumes that you are already familiar with XML such that your server-based applications serve up XML data exclusively, embed XML islands into HTML documents, or convert database data into XML. The focus of this chapter, and an extended application example of Chapter 57, is how to access custom elements that reside inside an IE XML element.

Elements and Nodes

Once you leave the specialized DOM vocabulary of HTML elements, the world can appear rather primitive — a highly granular world of node hierarchies, elements, element attributes, and node data. This granularity is a necessity in an environment in which the elements are far from generic and the structure of data in a document does not have to follow a format handed down from above. One Web application can

In This Chapter

Treating XML elements as objects

Creating IE XML data islands

Accessing XML element attributes

describe an individual's contact information with one set of elements, while another application uses a completely different approach to element names, element nesting, and their sequence.

Fortunately, most, if not all, scripting you do on XML data is on data served up by your own applications. Therefore, you know what the structure of the data is—or you know enough of it to let your scripts access the data.

The discussion of the W3C DOM in Chapter 14 should serve as a good introduction to the way you need to think about elements and their content. All relevant properties and methods are listed among the items shared by all elements in Chapter 15.

Note

Microsoft has created a separate document object model exclusively for XML documents. To distinguish between the DOMs for XML and HTML documents, Microsoft calls the former the XML DOM and the latter the DHTML DOM. Specifications for the two DOMs overlap in some terminology, but the two models are not interchangeable. Read more about the Microsoft XML DOM at <http://msdn.microsoft.com>.

An XML *data island* is a hierarchy of nodes. Typically, the outermost nodes are elements. Some elements have attributes, each of which is a typical name/value pair. Some elements have data that goes between the start and end tags of the element (such data is a text node nested inside the element node). And some elements can have both attributes and data. When an XML island contains the equivalent of multiple database records, an element container whose tag name is the same as each of the other records surrounds each record. Thus, the `getElementsByTagName()` method frequently accesses a collection of like-named elements.

Once you have a reference to an element node, you can reference that element's attributes as properties; however, a more formal access route is via the `getAttribute()` method of the element. If the element has data between its start and end tags, you can access that data from the element's reference by calling the `firstChild.data` property (although you may want to verify that the element has a child node of the text type before committing to retrieving the data).

Of course, your specific approach to XML elements and their data varies with what you intend to script with the data. For example, you may wish to do nothing more with scripting than enable a different style sheet for the data based on a user choice. The evolving XSL (eXtensible Stylesheet Language) standard is a kind of (non-JavaScript) scripting language for transforming raw XML data into a variety of presentations. But you can still use JavaScript to connect user-interface elements that control which of several style sheets renders the data. Or, as demonstrated in Chapters 52 and 57, you may wish to use JavaScript for more explicit control over the data and its rendering, taking advantage of JavaScript sorting and data manipulation facilities along the way.

Table 33-1 is a summary of W3C DOM Core objects, properties, and methods that you are most likely to use in extracting data from XML elements. You can find details of all of these items in Chapter 15.

Table 33-1 Properties and Methods for XML Element Reading

<i>Property or Method</i>	<i>Description</i>
<code>Node.nodeValue</code>	Data of a text node
<code>Node.nodeType</code>	Which node type
<code>Node.parentNode</code>	Reference to parent node
<code>Node.childNodes</code>	Array of child nodes
<code>Node.firstChild</code>	First of all child nodes
<code>Node.lastChild</code>	Last of all child nodes
<code>Node.previousSibling</code>	Previous node at same level
<code>Node.nextSibling</code>	Next node at same level
<code>Element.parentNode</code>	Reference to parent node
<code>Element.childNodes</code>	Array of child nodes
<code>Element.firstChild</code>	First of all child nodes
<code>Element.lastChild</code>	Last of all child nodes
<code>Element.previousSibling</code>	Previous node at same level
<code>Element.nextSibling</code>	Next node at same level
<code>Element.tagName</code>	Tag name
<code>Element.getAttribute(<i>name</i>)</code>	Retrieves attribute (Attr) object
<code>Element.getElementsByTagName(<i>name</i>)</code>	Array of nested, named elements
<code>Attr.name</code>	Name part of attribute object's name/ value pair
<code>Attr.value</code>	Value part of attribute object's name/ value pair

XML Element Object

For HTML element properties, methods, and event handlers, see Chapter 15.

<i>Properties</i>	<i>Methods</i>	<i>Event Handlers</i>
<code>src</code>		
<code>XMLDocument</code>		

Syntax

Accessing XML element object properties or methods:

```
(IE5+) [window.]document.all.elementID.property | method([parameters])
```

About this object

The XML element object is the primary container of an XML data island within an HTML page. If your scripts intend to traverse the node hierarchy within the element, or simply access properties of nested elements, then you should assign an identifier to the ID attribute of the XML element. For example, if the XML data contains results from a database query for music recordings that match some user-entered criteria, each returned record might be denoted as a RECORDING element as follows:

```
<XML ID="results">
  <SEARCHRESULTS>
    <RECORDING>
      ...elements with details...
    </RECORDING>
    <RECORDING>
      ...elements with details...
    </RECORDING>
    <RECORDING>
      ...elements with details...
    </RECORDING>
  </SEARCHRESULTS>
</XML>
```

Your script can now obtain an array of references to RECORDING elements as follows:

```
var recs = document.getElementById("results").getElementsByTagName("RECORDING")
```

While it is also true that there is no known HTML element with the tag name RECORDING (which enables you to use `document.getElementsByTagName("RECORDING")`), the unpredictability of XML data element names is reason enough to limit the scope of the `getElementsByTagName()` method to the XML data island.

Interestingly, the W3C DOM Level 2 does not define an XML element object within the HTML section. You cannot simply embed an XML document inside an HTML document: The standards clearly indicate that a document can be one or the other, but not both. While the NN6 DOM can recognize custom elements, the browser understandably gets confused when custom elements have tag names that already belong to the HTML DTD. Therefore, I do not recommend attempting to embed custom elements into an HTML document for NN6 unless it some day implements a mechanism similar to IE's XML data islands.

Note

IE5/Macintosh does not support XML data islands.

Properties

src

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

The `src` property represents the `SRC` attribute of the XML element. The attribute points to the URL of an external XML document whose data is embedded within the current HTML document.

XMLDocument

Value: Object Reference

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

The `XMLDocument` property returns a reference to Microsoft's proprietary XML document object and the object model associated with it (the so-called XML DOM). A lot of this object model is patterned after the W3C DOM model, but access to these properties is via a rather roundabout way. For more details, visit

CHAPTER

The String Object

Chapter 6's tutorial introduced you to the concepts of values and the types of values that JavaScript works with—features, such as strings, numbers, and Boolean values. In this chapter, you look more closely at the very important String data type, as well as its relationship to the Number data type. Along the way, you encounter the many ways in which JavaScript enables scripters to manipulate strings.

Note

Much of the syntax that you see in this chapter is identical to that of the Java programming language. Because the scope of JavaScript activity is narrower than that of Java, you don't have nearly as much to learn for JavaScript as for Java. At the same time, certain string object language features apply to scripting but not to Java programming. Improvements to the string object's methods in Navigator 4 greatly simplify a number of string manipulation tasks. If you must script for a lower common denominator of browser, however, you may need some of the same kind of string micro-management skills that a C programmer needs. I soften the blow by providing some general purpose functions that you can plug into your scripts to make those jobs easier.

String and Number Data Types

Although JavaScript is not what is known as a “strongly typed” language, you still need to be aware of several data types because of their impact on the way you work with the information in those forms. In this section, I focus on strings and two types of numbers.

Simple strings

A *string* consists of one or more standard text characters between matching quote marks. JavaScript is forgiving in one regard: You can use single or double quotes, as long as you match two single quotes or two double quotes around a

In This Chapter

How to parse and work with text

Performing search-and-replace operations

Scripted alternatives to text formatting

string. Another benefit to this scheme becomes apparent when you try to include a quoted string inside a string. For example, say that you're assembling a line of HTML code in a variable that you will eventually write to a new window completely controlled by JavaScript. The line of text that you want to assign to a variable is the following:

```
<INPUT TYPE="checkbox" NAME="candy">Chocolate
```

To assign this entire line of text to a variable, you have to surround the line in quotes. But because quotes appear inside the string, JavaScript (or any language) has problems deciphering where the string begins or ends. By carefully placing the other kind of quote pairs, however, you can make the assignment work. Here are two equally valid ways:

```
result = '<INPUT TYPE="checkbox" NAME="candy">Chocolate'  
result = "<INPUT TYPE='checkbox' NAME='candy'>Chocolate"
```

Notice that in both cases, the same unique pair of quotes surrounds the entire string. Inside the string, two quoted strings appear that are treated as such by JavaScript. I recommend that you settle on one form or the other, and then use that form consistently throughout your scripts.

Building long string variables

The act of joining strings together — concatenation — enables you to assemble long strings out of several little pieces. This feature is very important for some of your scripting — for example, when you need to build an HTML page's specifications entirely within a variable before writing the page to another frame with one `document.write()` statement.

One tactic that I use keeps the length of each statement in this building process short enough so that it's easily readable in your text editor. This method uses the add-by-value assignment operator (`+=`) that appends the right-hand side of the equation to the left-hand side. Here is a simple example, which begins by initializing a variable as an empty string:

```
var newDocument = ""  
newDocument += "<HTML><HEAD><TITLE>Life and Times</TITLE></HEAD>"  
newDocument += "<BODY><H1>My Life and Welcome to It</H1>"  
newDocument += "by Sidney Finortny<HR>"
```

Starting with the second line, each statement adds more data to the string being stored in `newDocument`. You can continue appending string data until the entire page's specification is contained in the `newDocument` variable.

Joining string literals and variables

In some cases, you need to create a string out of literal strings (characters with quote marks around them) and string variable values. The methodology for concatenating these types of strings is no different from that of multiple string literals. The plus-sign operator does the job. Therefore, in the following example, a variable contains a name. That variable value is made a part of a larger string whose other parts are string literals:

```
yourName = prompt("Please enter your name:","")
var msg = "Good afternoon, " + yourName + "."
alert(msg)
```

Some common problems that you may encounter while attempting this kind of concatenation include the following:

- ♦ Accidentally omitting one of the quotes around a literal string
- ♦ Failing to insert blank spaces in the string literals to accommodate word spaces
- ♦ Forgetting to concatenate punctuation after a variable value

Also, don't forget that what I show here as variable values can be any expression that evaluates to a string, including property references and the results of some methods. For example

```
var msg = "The name of this document is " + document.title + "."
alert(msg)
```

Special inline characters

The way string literals are created in JavaScript makes adding certain characters to strings difficult. I'm talking primarily about adding quotes, carriage returns, apostrophes, and tab characters to strings. Fortunately, JavaScript provides a mechanism for entering such characters into string literals. A backslash symbol, followed by the character that you want to appear as inline, makes that task happen. For the "invisible" characters, a special set of letters following the backslash tells JavaScript what to do.

The most common backslash pairs are as follows:

- ♦ `\"` Double quote
- ♦ `\'` Single quote (apostrophe)
- ♦ `\\` Backslash
- ♦ `\b` Backspace
- ♦ `\t` Tab
- ♦ `\n` New line
- ♦ `\r` Carriage return
- ♦ `\f` Form feed

Use these "inline characters" (also known as "escaped characters," but this terminology has a different connotation for Internet strings) inside quoted string literals to make JavaScript recognize them. When assembling a block of text that needs a new paragraph, insert the `\n` character pair. Here are some examples of syntax using these special characters:

```
msg = "You\'re doing fine."
msg = "This is the first line.\nThis is the second line."
msg = document.title + "\n" + document.links.length + " links present."
```

Technically speaking, a complete carriage return, as known from typewriting days, is both a line feed (advance the line by one) and a carriage return (move the carriage all the way to the left margin). Although JavaScript strings treat a line feed (`\n` new line) as a full carriage return, you may have to construct `\r\n` breaks when assembling strings that go back to a CGI script on a server. The format that you use all depends on the string-parsing capabilities of the CGI program. (Also see the special requirements for the `TEXTAREA` object in Chapter 22.)

Confusing the strings assembled for display in `TEXTAREA` objects or alert boxes with strings to be written as HTML is easy. For HTML strings, make sure that you use the standard HTML tags for line breaks (`
`) and paragraph breaks (`<P>`) rather than the inline return or line feed symbols.

†Member of the static String object

Syntax

Creating a string object:

```
var myString = new String("characters")
```

Accessing static String object properties and methods:

```
String.property | method([parameters])
```

Accessing string object properties and methods:

```
string.property | method([parameters])
```

About this object

JavaScript draws a fine line between a string value and a string object. Both let you use the same methods on their contents, so that by and large, you do not have to create a string object (with the `new String()` constructor) every time you want to assign a string value to a variable. A simple assignment operation (`var myString = "fred"`) is all you need to create a string value that behaves on the surface very much like a full-fledged string object.

Where the difference comes into play is when you want to exploit the “object-ness” of a genuine string object, which I explain further in the discussion of the `string.prototype` property later in this chapter. You may also encounter the need to use a full-fledged string object when passing string data to Java applets. If you find that your applet doesn’t receive a string value as a Java String data type, then create a new string object via the JavaScript constructor function before passing the value onto the applet.

With string data often comes the need to massage that text in scripts. In addition to concatenating strings, you at times need to extract segments of strings, delete parts of strings, and replace one part of a string with some other text. Unlike many

plain-language scripting languages, JavaScript is fairly low-level in its built-in facilities for string manipulation. This characteristic means that unless you can take advantage of the regular expression powers of NN4+ and IE4+, you must fashion your own string handling routines out of very elemental powers built into JavaScript. Later in this chapter, I provide several functions that you can use in your own scripts for common string handling in a manner fully compatible with older browsers.

As you work with string values, visualize every string value as an object with properties and methods like other JavaScript objects. The latest versions of JavaScript define a few properties and a slew of methods for any string value (and one extra property for the static `String` object that is always present in the context of the browser window). The syntax is the same for string methods as it is for any other object method:

```
stringObject.method()
```

What may seem odd at first is that the `stringObject` part of this reference can be any expression that evaluates to a string, including string literals, variables containing strings, methods or functions that return strings, or other object properties. Therefore, the following examples of calling the `toUpperCase()` method are all valid:

```
"george burns".toUpperCase()
yourName.toUpperCase() // yourName is a variable containing a string
window.prompt("Enter your name","").toUpperCase()
document.forms[0].entry.value.toUpperCase() // entry is a text field object
```

An important concept to remember is that invoking a string method does not change the string object that is part of the reference. Rather, the method returns a value, which can be used as a parameter to another method or function call, or assigned to a variable value.

Therefore, to change the contents of a string variable to the results of a method, you must use an assignment operator, as in

```
yourName = yourName.toUpperCase() // variable is now all uppercase
```

Note

In Navigator 2, avoid nesting method calls for the same string object when the methods modify the string. The evaluation does not work as you may expect. Instead, break out each call as a separate JavaScript statement.

Properties constructor

Value: Function Reference

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The `constructor` property is a reference to the function that was invoked to create the current string. For a native JavaScript string object, the constructor function is the built-in `String()` constructor.

When you use the new `String()` constructor to create a string object, the type of the value returned by the constructor is `object` (meaning the `typeof` operator returns `object`). Therefore, you can use the `constructor` property on an object value to see if it is a string object:

```
if (typeof someValue == "object" ) {
    if (someValue.constructor == String) {
        // statements to deal with string object
    }
}
```

Although the property is read/write, and you can assign a different constructor to the `String.prototype`, the native behavior of a `String` object persists through the new constructor.

Example on the CD-ROM

Related Items: `prototype` property.

length

Value: Integer

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

The most frequently used property of a string is `length`. To derive the length of a string, read its property as you would read the `length` property of any object:
`string.length`

The `length` value represents an integer count of the number of characters within the string. Spaces and punctuation symbols count as characters. Any backslash special characters embedded in a string count as one character, including such characters as newline and tab. Here are some examples:

```
"Lincoln".length // result = 7
"Four score".length // result = 10
"One\two".length // result = 7
"".length // result = 0
```

The `length` property is commonly summoned when dealing with detailed string manipulation in repeat loops.

prototype

Value: Object

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓			✓	✓	✓

String objects defined with the new `String("stringValue")` constructor are robust objects compared with plain, old variables that are assigned string values. You certainly don't have to create this kind of string object for every string in your scripts, but these objects do come in handy if you find that strings in variables go awry. This happens occasionally while trying to preserve string information as script variables in other frames or windows. By using the string object constructor, you can be relatively assured that the string value will be available in the distant frame when needed.

Another byproduct of true string objects is that you can assign prototype properties and methods to all string objects in the document. A *prototype* is a property or method that becomes a part of every new object created after the prototype items are added. For strings, as an example, you may want to define a new method for converting a string into a new type of HTML font tag not already defined by the JavaScript string object. Listing 34-1 shows how to create and use such a prototype.

Listing 34-1: A String Object Prototype

```
<HTML>
<HEAD>
<TITLE>String Object Prototype</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
function makeItHot() {
    return "<FONT COLOR='red'>" + this.toString() + "</FONT>"
}
String.prototype.hot = makeItHot
</SCRIPT>
<BODY>
<SCRIPT LANGUAGE="JavaScript1.1">
document.write("<H1>This site is on " + "FIRE".hot() + "!!</H1>")
</SCRIPT>
</BODY>
</HTML>
```

A function definition (`makeItHot()`) accumulates string data to be returned to the object when the function is invoked as the object's method. The `this` keyword refers to the object making the call, which you convert to a string for concatenation with the rest of the strings to be returned. In the page's Body, that prototype method is invoked in the same way one invokes existing `String` methods that turn strings into HTML tags (discussed later in this chapter).

In the next sections, I divide string object methods into two distinct categories. The first, parsing methods, focuses on string analysis and character manipulation within strings. The second group, formatting methods, is devoted entirely to assembling strings in HTML syntax for those scripts that assemble the text to be written into new documents or other frames.

Parsing methods

string.charAt(index)

Returns: One-Character String

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Use the *string.charAt()* method to read a single character from a string when you know the position of that character. For this method, you specify an index value in the string as a parameter to the method. The index value of the first character of the string is 0. To grab the last character of a string, mix string methods: `myString.charAt(myString.length - 1)`

If your script needs to get a range of characters, use the *string.substring()* method. Using *string.substring()* to extract a character from inside a string is a common mistake, when the *string.charAt()* method is more efficient.

Example on the CD-ROM

Related Items: `string.lastIndexOf()`, `string.indexOf()`, `string.substring()` methods.

string.charCodeAt([index])

`String.fromCharCode(num1 [, num2 [, ... numn]])`

Returns: Integer code number for a character; concatenated string value of code numbers supplied as parameters.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Conversions from plain language characters to their numeric equivalents have a long tradition in computer programming. For a long time, the most common numbering scheme was the ASCII standard, which covers the basic English,

alphanumeric characters and punctuation within 128 values (numbered 0 through 127). An extended version with a total of 256 characters, with some variations depending on the operating system, accounts for other roman characters in other languages, particularly vowels with umlauts and other pronunciation marks. To bring all languages, including pictographic languages and other nonroman alphabets, into the computer age, a world standard called Unicode provides space for thousands of characters.

In JavaScript, the character conversions are string methods. Acceptable values depend on the browser that you are using. NN4 works only with the 256 ISO-Latin-I values; NN6 and IE4+ work with the Unicode system.

The two methods that perform these conversions work in very different ways syntactically. The first, `string.charCodeAt()`, converts a single string character to its numerical equivalent. The string being converted is the one to the left of the method name — and the string may be a literal string or any other expression that evaluates to a string value. If no parameter is passed, the character being converted is by default the first character of the string. However, you can also specify a different character as an index value into the string (first character is 0), as demonstrated here:

```
"abc".charCodeAt() // result = 97
"abc".charCodeAt(0) // result = 97
"abc".charCodeAt(1) // result = 98
```

If the string value is an empty string or the index value is beyond the last character, the result is NaN.

To convert numeric values to their characters, use the `String.fromCharCode()` method. Notice that the object beginning the method call is the static `String` object, not a string value. Then, as parameters, you can include one or more integers separated by commas. In the conversion process, the method combines the characters for all of the parameters into one string, an example of which is shown here:

```
String.fromCharCode(97, 98, 99) // result "abc"
```

**Note**

The `string.charCodeAt()` method is broken on the first release of the Macintosh version of Navigator 4, and always returns NaN. This error is fixed in subsequent releases.

**On the
CD-ROM**

Example (with Listing 34-2) on the CD-ROM

Related Items: None.

*string.concat(string2)***Returns:** Combined string.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

JavaScript's add-by-value operator (`+=`) provides a convenient way to concatenate strings. Recent browsers, however, include a string object method that performs the same task. The base string to which more text is appended is the object or value to the left of the period. The string to be appended is the parameter of the method, as the following example demonstrates:

```
"abc".concat("def") // result: "abcdef"
```

As with the add-by-value operator, the `concat()` method doesn't know about word endings. You are responsible for including the necessary space between words if the two strings require a space between them in the result.

Related Items: Add-by-value (`+=`) operator.

*string.indexOf(searchString [, startIndex])***Returns:** Index value of the character within *string* where *searchString* begins.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Like some languages' offset string function, JavaScript's `indexOf()` method enables your script to obtain the number of the character in the main string where a search string begins. Optionally, you can specify where in the main string the search should begin — but the returned value is always relative to the very first character of the main string. Such as all string object methods, index values start their count with 0. If no match occurs within the main string, the returned value is -1. Thus, this method is a convenient way to determine whether one string contains another, regardless of position.

A bug exists in some versions of Navigator 2 and 3 that can trip up your scripts if you don't guard against it. If the string being searched is empty, the `indexOf()` method returns an empty string rather than the expected -1 value. Therefore, you may want to test to make sure the string is not empty before applying this method. A look at the following examples tells you more about this method than a long description. In all examples, you assign the result of the method to a variable named `offset`.

Example on the CD-ROM

Related Items: `string.lastIndexOf()`, `string.charAt()`, `string.substring()` methods.

string.lastIndexOf(*searchString*[, *startIndex*])

Returns: Index value of the last character within *string* where *searchString* begins.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

The `string.lastIndexOf()` method is closely related to the method `string.indexOf()`. The only difference is that this method starts its search for a match from the end of the string (`string.length - 1`) and works its way backward through the string. All index values are still counted, starting with 0, from the front of the string. The examples that follow use the same values as in the examples for `string.indexOf()` so that you can compare the results. In cases where only one instance of the search string is found, the results are the same; but when multiple instances of the search string exist, the results can vary widely—hence the need for this method.

Caution

This string method has experienced numerous bugs, particularly in Navigator 2, and in later versions for UNIX. Scripts using this method should be tested exhaustively.

On the CD-ROM

Example on the CD-ROM

Related Items: `string.lastIndexOf()`, `string.charAt()`, `string.substring()` methods.

string.localeCompare(*string2*)

Returns: Integer.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `localeCompare()` method lets a script compare the cumulative Unicode values of two strings, taking into account the language system for the browser. The need for this method affects only some language systems (Turkish is said to be one). If the two strings, adjusted for the language system, are equal, the value

returned is zero. If the string value on which the method is invoked (meaning the string to the left of the period) sorts ahead of the parameter string, the value returned is a negative integer; otherwise the returned value is a positive integer.

The ECMA standard for this method leaves the precise positive or negative values up to the browser designer. NN6 calculates the cumulative Unicode values for both strings and subtracts the string parameter's sum from the string value's sum. IE5.5, on the other hand, returns -1 or 1 if the strings are not colloquially equal.

Related Items: `string.toLocaleLowerCase()`, `string.toLocaleUpperCase()` methods.

string.match(regExpression)

Returns: Array of matching strings.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The `string.match()` method relies on the `RegExp` (regular expression) object introduced to JavaScript in NN4 and IE4. The string value under scrutiny is to the left of the dot, while the regular expression to be used by the method is passed as a parameter. The parameter must be a regular expression object, created according to the two ways these objects can be generated.

This method returns an array value when at least one match turns up; otherwise the returned value is `null`. Each entry in the array is a copy of the string segment that matches the specifications of the regular expression. You can use this method to uncover how many times a substring or sequence of characters appears in a larger string. Finding the offset locations of the matches requires other string parsing.

Example (with Listing 34-3) on the CD-ROM

Related Items: `RegExp` object (Chapter 38).

string.replace(regExpression, replaceString)

Returns: Changed string.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Regular expressions are commonly used to perform search-and-replace operations. JavaScript's `string.replace()` method provides a simple framework in which to perform this kind of operation on any string.

Searching and replacing requires three components. The first is the main string that is the target of the operation. Second is the regular expression to search for. And third is the string to replace each instance of the text found by the operation. For the `string.replace()` method, the main string is the string value or object referenced to the left of the period. This string can also be a literal string (that is, text surrounded by quotes). The regular expression to search for is the first parameter, while the replacement string is the second parameter.

The regular expression definition determines whether the replacement is of just the first match encountered in the main string or all matches in the string. If you add the `g` parameter to the end of the regular expression, then one invocation of the `replace()` method performs global search-and-replace through the entire main string.

As long as you know how to generate a regular expression, you don't have to be a whiz to use the `string.replace()` method to perform simple replacement operations. But using regular expressions can make the operation more powerful. Consider these soliloquy lines by Hamlet:

```
To be, or not to be: that is the question:
Whether 'tis nobler in the mind to suffer
```

If you wanted to replace both instances of “be” with “exist,” you can do it in this case by specifying

```
var regexp = /be/g
soliloquy.replace(regexp, "exist")
```

But you can't always be assured that the letters “b” and “e” will be standing alone as a word. What happens if the main string contains the word “being” or “saber”? The above example replaces the “be” letters in them as well.

The regular expression help comes from the special characters to better define what to search for. In the example here, the search is for the word “be.” Therefore, the regular expression surrounds the search text with word boundaries (the `\b` special character), as in

```
var regexp = /\bbe\b/g
soliloquy.replace(regexp, "exist")
```

This syntax also takes care of the fact that the first two “be” words are followed by punctuation, rather than a space, as you may expect for a freestanding word. For more about regular expression syntax, see Chapter 38.

Example (with Listing 34-4) on the CD-ROM

Related Items: `string.match()` method; `RegExp` object.

string.search(*regExpression*)**Returns:** Offset Integer.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The results of the *string*.search() method may remind you of the *string*.indexOf() method. In both cases, the returned value is the character number where the matching string first appears in the main string, or -1 if no match occurs. The big difference, of course, is that the matching string for *string*.search() is a regular expression.

Example on the CD-ROM

Related Items: *string*.match() method; RegExp object.*string*.slice(*startIndex* [, *endIndex*])**Returns:** String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The *string*.slice() method resembles the method *string*.substring() in that both let you extract a portion of one string and create a new string as a result (without modifying the original string). A helpful improvement in *string*.slice(), however, is that specifying an ending index value relative to the end of the main string is easier.

Using *string*.substring() to extract a substring that ends before the end of the string requires machinations, such as the following:

```
string.substring(4, (string.length-2))
```

Instead, you can assign a negative number to the second parameter of *string*.slice() to indicate an offset from the end of the string:

```
string.slice(4, -2)
```

The second parameter is optional. If you omit the second parameter, the returned value is a string from the starting offset to the end of the main string.

Example (with Listing 34-5) on the CD-ROM

Related Items: `string.substr()`, `string.substring()` methods.

string.split("delimiterCharacter" [, limitInteger])

Returns: Array of delimited items.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓			✓	✓	✓

The `split()` method is the functional opposite of the `array.join()` method (see Chapter 37). From the string object point of view, JavaScript splits a long string into pieces delimited by a specific character and then creates a dense array with those pieces. You do not need to initialize the array via the new `Array()` constructor. Given the powers of array object methods, such as `array.sort()`, you may want to convert a series of string items to an array to take advantage of those powers. Also, if your goal is to divide a string into an array of single characters, you can still use the `split()` method, but specify an empty string as a parameter. For NN3 and IE4, only the first parameter is observed.

In NN4+ and IE4+, you can use a regular expression object for the first parameter, enhancing the powers of finding delimiters in strings. For example, consider the following string:

```
var nameList = "1.Fred,2.Jane,3.Steve"
```

To convert that string into a three-element array of only the names takes a lot of parsing without regular expressions before you can even use `string.split()`. However, with a regular expression as a parameter,

```
var regexp = /,*\d.\b/
var newArray = nameList.split(regexp)
// result = an array "Fred", "Jane", "Steve"
```

the new array entries hold only the names and not the leading numbers or periods. A second addition is an optional second parameter. This integer value allows you to specify a limit to the number of array elements generated by the method.

And finally, NN4+ provides some extra (but non-ECMA-standard) functionality if you use the `string.split()` method inside a `<SCRIPT>` tag that specifies JavaScript1.2 (only). A space character as a single parameter, such as `string.split(" ")`, is interpreted to mean any white space (spaces, tabs, carriage returns, line feeds) between runs of characters. Even if the number of spaces between elements is not uniform, they are treated all the same. This special feature may not be adopted by ECMA and is omitted from later JavaScript versions in NN.

Example on the CD-ROM

Related Items: `array.join()` method.

*string.substr(start [, length])***Returns:** String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The *string.substr()* method offers a variation of the *string.substring()* method that has been in the language since the beginning. The distinction is that the *string.substr()* method's parameters specify the starting index and a number of characters to be included from that start point. In contrast, the *string.substring()* method parameters specify index points for the start and end characters within the main string.

As with all string methods requiring an index value, the *string.substr()* first parameter is zero-based. If you do not specify a second parameter, the returned substring starts at the indexed point and extends to the end of the string. A second parameter value that exceeds the end point of the string means that the method returns a substring to the end of the string.

Even though this method is newer than its partner, it is not part of the ECMA standard as of Edition 3 of the language spec. But because the method is so widely used, the standard does acknowledge it so that other scripting contexts can implement the method consistent with browser practice.

**Caution**

NN4/Mac users should avoid setting the second parameter to a negative number to prevent a crash.

**On the CD-ROM**

Example (with Listing 34-6) on the CD-ROM

Related Items: *string.substring()* method.*string.substring(indexA, indexB)***Returns:** String of characters between index values *indexA* and *indexB*.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

The *string.substring()* method enables your scripts to extract a copy of a contiguous range of characters from any string. The parameters to this method are the starting and ending index values (first character of the string object is index value 0) of the main string from which the excerpt should be taken. An important

item to note is that the excerpt goes up to, but does not include, the character pointed to by the higher index value.

It makes no difference which index value in the parameters is larger than the other: The method starts the excerpt from the lowest value and continues to (but does not include) the highest value. If both index values are the same, the method returns an empty string; and if you omit the second parameter, the end of the string is assumed to be the endpoint.

**Note**

NN4 experimented with a slight variation of this method. If you use this method in a `<SCRIPT LANGUAGE="JavaScript1.2">` tag, the first index value is always the start of the excerpt, and the end is at the second index value, even if it means that the string value comes out in reverse. This variation has not been carried forward in later versions of JavaScript in NN.

**On the CD-ROM**

Example (with Listing 34-7) on the CD-ROM

Related Items: `string.substr()`, `string.slice()` methods.

string.toLocaleLowerCase()
string.toLocaleUpperCase()

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

These two methods are variations on the standard methods for changing the case of a string. They take into account some language systems whose cases for a particular character don't necessarily map to the Latin alphabet character mappings.

Related Items: `string.toLowerCase()`, `string.toUpperCase()` methods.

string.toLowerCase()
string.toUpperCase()

Returns: The string in all lower- or uppercase, depending on which method you invoke.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

A great deal of what takes place on the Internet (and in JavaScript) is case-sensitive. URLs on some servers, for instance, are case-sensitive for directory names and filenames. These two methods, the simplest of the string methods, return a copy of a string converted to either all lowercase or all uppercase. Any mixed-case strings get converted to a uniform case. If you want to compare user input from a field against some coded string without worrying about matching case, you can convert both strings to the same case for the comparison.

Example on the CD-ROM

Related Items: `string.toLocaleLowerCase()`, `string.toLocaleUpperCase()` methods.

string.toString()
string.valueOf()

Returns: String value.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Both of these methods return string values (as opposed to full-fledged string objects). If you have created a string object via the new `String()` constructor, the type of that item is `object`. Therefore, if you want to examine more precisely what kind of value is held by the object, you can use the `valueOf()` method to get the value and then examine it via the `typeof` operator. The `toString()` method is present for this object primarily because a string object inherits the method from the root object of JavaScript.

Example on the CD-ROM

Related Items: `typeof` operator (Chapter 40).

String Utility Functions

Figuring out how to apply the various string object methods to a string manipulation challenge is not always an easy task, especially if you need backward compatibility with older scriptable browsers. I also find it difficult to anticipate every possible way you may need to massage strings in your scripts. But to help

you get started, Listing 34-8 contains a library of string functions for inserting, deleting, and replacing chunks of text in a string. If your audience uses browsers capable of including external .js library files, that would be an excellent way to make these functions available to your scripts.

Listing 34-8: Utility String Handlers

```
// extract front part of string prior to searchString
function getFront(mainStr,searchStr){
    foundOffset = mainStr.indexOf(searchStr)
    if (foundOffset == -1) {
        return null
    }
    return mainStr.substring(0,foundOffset)
}

// extract back end of string after searchString
function getEnd(mainStr,searchStr) {
    foundOffset = mainStr.indexOf(searchStr)
    if (foundOffset == -1) {
        return null
    }
    return mainStr.substring(foundOffset+searchStr.length,mainStr.length)
}

// insert insertString immediately before searchString
function insertString(mainStr,searchStr,insertStr) {
    var front = getFront(mainStr,searchStr)
    var end = getEnd(mainStr,searchStr)
    if (front != null && end != null) {
        return front + insertStr + searchStr + end
    }
    return null
}

// remove deleteString
function deleteString(mainStr,deleteStr) {
    return replaceString(mainStr,deleteStr,"")
}

// replace searchString with replaceString
function replaceString(mainStr,searchStr,replaceStr) {
    var front = getFront(mainStr,searchStr)
    var end = getEnd(mainStr,searchStr)
    if (front != null && end != null) {
        return front + replaceStr + end
    }
    return null
}
```

The first two functions extract the front or end components of strings as needed for some of the other functions in this suite. The final three functions are the core of these string-handling functions. If you plan to use these functions in your scripts, be sure to notice the dependence that some functions have on others. Including all five functions as a group ensures that they work as designed.

Formatting methods

Now we come to the other group of string object methods, which ease the process of creating the numerous string display characteristics when you use JavaScript to assemble HTML code. The following is a list of these methods:

<code>string.anchor("anchorName")</code>	<code>string.link(locationOrURL)</code>
<code>string.blink()</code>	<code>string.big()</code>
<code>string.bold()</code>	<code>string.small()</code>
<code>string.fixed()</code>	<code>string.strike()</code>
<code>string.fontcolor(colorValue)</code>	<code>string.sub()</code>
<code>string.fontSize(integer1to7)</code>	<code>string.sup()</code>
<code>string.italics()</code>	

First examine the methods that don't require any parameters. You probably see a pattern: All of these methods are font-style attributes that have settings of on or off. To turn on these attributes in an HTML document, you surround the text in the appropriate tag pairs, such as `...` for boldface text. These methods take the string object, attach those tags, and return the resulting text, which is ready to be put into any HTML that your scripts are building. Therefore, the expression

```
"Good morning!".bold()
```

evaluates to

```
<B>Good morning!</B>
```

Of course, nothing is preventing you from building your HTML by embedding real tags instead of by calling the string methods. The choice is up to you. One advantage to the string methods is that they never forget the ending tag of a tag pair. Listing 34-9 shows an example of incorporating a few simple string methods in a string variable that is eventually written to the page as it loads. Internet Explorer does not support the `<BLINK>` tag and therefore ignores the `string.blink()` method.

Listing 34-9: Using Simple String Methods

```
<HTML>
<HEAD>
<TITLE>HTML by JavaScript</TITLE>
</HEAD>

<BODY>
<SCRIPT LANGUAGE="JavaScript">
var page = ""
```

Continued

Listing 34-9 (continued)

```

page += "JavaScript can create HTML on the fly.<P>Numerous string object methods
facilitate creating text that is " + "boldfaced".bold() + ", " +
"italicized".italics() + ", or even the terribly annoying " + "blinking
text".blink() + "."
document.write(page)
</SCRIPT>
</BODY>
</HTML>

```

Of the remaining string methods, two more (*string.fontSize()* and *string.fontcolor()*) also affect the font characteristics of strings displayed in the HTML page. The parameters for these items are pretty straightforward—an integer between 1 and 7 corresponding to the seven browser font sizes and a color value (as either a hexadecimal triplet or color constant name) for the designated text. Listing 34-10 adds a line of text to the string of Listing 34-9. This line of text not only adjusts the font size of some parts of the string but also nests multiple attributes inside one another to set the color of one word in a large-font-size string. Because these string methods do not change the content of the string, you can safely nest methods here.

Listing 34-10: Nested String Methods

```

<HTML>
<HEAD>
<TITLE>HTML by JavaScript</TITLE>
</HEAD>

<BODY>
<SCRIPT LANGUAGE="JavaScript">
var page = ""
page += "JavaScript can create HTML on the fly.<P>Numerous string object methods
facilitate creating text that is " + "boldfaced".bold() + ", " +
"italicized".italics() + ", or even the terribly annoying " + "blinking
text".blink() + ".<P>"
page += "We can make " + "some words big".fontSize(5) + " and some words both "
+ ("big and " + "colorful".fontcolor('coral')).fontSize(5) + " at the same
time."
document.write(page)
</SCRIPT>
</BODY>
</HTML>

```

The final two string methods let you create an anchor and a link out of a string. The *string.anchor()* method uses its parameter to create a name for the anchor. Thus, the following expression

```
"Table of Contents".anchor("toc")
```

evaluates to

```
<A NAME="toc">Table of Contents</A>
```

In a similar fashion, the `string.link()` method expects a valid location or URL as its parameter, creating a genuine HTML link out of the string:

```
"Back to Home".link("index.html")
```

This evaluates to the following:

```
<A HREF="index.html">Back to Home</A>
```

Again, the choice of whether you use string methods to build HTML anchors and links over assembling the actual HTML is up to you. The methods may be a bit easier to work with if the values for the string and the parameters are variables whose content may change based on user input elsewhere in your Web site.

URL String Encoding and Decoding

When browsers and servers communicate, some non-alphanumeric characters that we take for granted (such as a space) cannot make the journey in their native form. Only a narrower set of letters, numbers, and punctuation is allowed. To accommodate the rest, the characters must be encoded with a special symbol (%) and their hexadecimal ASCII values. For example, the space character is hex 20 (ASCII decimal 32). When encoded, it looks like %20. You may have seen this symbol in browser history lists or URLs.

JavaScript includes two functions, `escape()` and `unescape()`, that offer instant conversion of whole strings. To convert a plain string to one with these escape codes, use the `escape` function, as in

```
escape("Howdy Pardner") // result = "Howdy%20Pardner"
```

The `unescape()` function converts the escape codes into human-readable form. Both of these functions and some newer, more robust versions for recent browsers are covered in Chapter 42.

35

CHAPTER

The Math, Number, and Boolean Objects

The introduction to data types and values in Chapter 6’s tutorial scratched the surface of JavaScript’s numeric and Boolean powers. In this chapter, you look more closely at JavaScript’s way of working with numbers and Boolean data.

Math often frightens away budding programmers; but as you’ve seen so far in this book, you don’t really have to be a math genius to program in JavaScript. The powers described in this chapter are here when you need them — if you need them. So if math is not your strong suit, don’t freak out over the terminology here.

An important point to remember about the objects described in this chapter is that (like string values and string objects) numbers and Booleans are both values and objects. Fortunately for script writers, the differentiation is rarely, if ever, a factor unless you get into some very sophisticated programming. To those who actually write the JavaScript interpreters inside the browsers we use, the distinctions are vital.

For most scripters, the information about numeric data types and conversions as well as the `Math` object are important to know. I present other details in this chapter about the number and Boolean objects primarily for completeness because their direct powers are almost never used in day-to-day scripting of Web applications.

Numbers in JavaScript

More powerful programming languages have many different kinds of numbers, each related to the amount of memory it occupies in the computer. Managing all these different types may be fun for some, but it gets in the way of quick scripting. A JavaScript number has only two possibilities. It can be an integer or a floating-point value. An *integer* is any whole number within a humongous range that does not have any fractional

In This Chapter

Advanced math operations

Number base conversions

Working with integers and floating-point numbers

part. Integers never contain a decimal point in their representation. *Floating-point numbers* in JavaScript spread across the same range, but they are represented with a decimal point and some fractional value. If you are an experienced programmer, refer to the discussion about the `Number` object later in this chapter to see how the JavaScript number type lines up with numeric data types you use in other programming environments.

Integers and floating-point numbers

Deep inside a computer, the microprocessor has an easier time performing math on integer values as compared to any number with a decimal value tacked on it, which requires the microprocessor to go through extra work to add even two such floating-point numbers. We, as scripters, are unfortunately saddled with this historical baggage and must be conscious of the type of number used in certain calculations.

Most internal values generated by JavaScript, such as index values and `length` properties, consist of integers. Floating-point numbers usually come into play as the result of the division of numeric values, special values such as `pi`, and human-entered values such as dollars and cents. Fortunately, JavaScript is forgiving if you try to perform math operations on mixed numeric data types. Notice how the following examples resolve to the appropriate data type:

```
3 + 4 = 7 // integer result
3 + 4.1 = 7.1 // floating-point result
3.9 + 4.1 = 8 // integer result
```

Of the three examples, perhaps only the last result is unexpected. When two floating-point numbers yield a whole number, the result is rendered as an integer.

When dealing with floating-point numbers, be aware that not all browser versions return the precise same value down to the last digit to the right of the decimal. For example, the following table shows the result of $8/9$ as calculated by numerous scriptable browsers (all Windows 95) and converted for string display:

Navigator 2	0.888888888888888884
Navigator 3	.8888888888888888
Navigator 4	.8888888888888888
Navigator 6	0.8888888888888888
Internet Explorer 3	0.888888888888889
Internet Explorer 4+	0.8888888888888888

Clearly, from this display, you don't want to use floating-point math in JavaScript browsers to plan space flight trajectories. For everyday math, however, you need to be cognizant of floating-point errors that accrue in PC arithmetic.

In Navigator, JavaScript relies on the operating system's floating-point math for its own math. Operating systems that offer accuracy to as many places to the right of the decimal as JavaScript displays are exceedingly rare. As you can detect from the preceding table, the modern versions of browsers from Netscape and Microsoft agree about how many digits to display and how to perform internal rounding for

this display. That's good for the math, but not particularly helpful when you need to display numbers in a specific format.

Until you get to IE5.5 and NN6, JavaScript does not offer built-in facilities for formatting the results of floating-point arithmetic. (For the newer browsers, see the `Number` object later in this chapter for formatting methods.) Listing 35-1 demonstrates a generic formatting routine for positive values, plus a specific call that turns a value into a dollar value. Remove the comments and the routine is fairly compact.

Listing 35-1: A Generic Number-Formatting Routine

```
<HTML>
<HEAD>
<TITLE>Number Formatting</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// generic positive number decimal formatting function
function format (expr, decplaces) {
    // raise incoming value by power of 10 times the
    // number of decimal places; round to an integer; convert to string
    var str = "" + Math.round (eval(expr) * Math.pow(10,decplaces))
    // pad small value strings with zeros to the left of rounded number
    while (str.length <= decplaces) {
        str = "0" + str
    }
    // establish location of decimal point
    var decpoint = str.length - decplaces
    // assemble final result from: (a) the string up to the position of
    // the decimal point; (b) the decimal point; and (c) the balance
    // of the string. Return finished product.
    return str.substring(0,decpoint) + "." + str.substring(decpoint,str.length);
}
// turn incoming expression into a dollar value
function dollarize (expr) {
    return "$" + format(expr,2)
}
</SCRIPT>
</HEAD>
<BODY>
<H1>How to Make Money</H1>
<FORM>
Enter a positive floating-point value or arithmetic expression to be converted
to a currency format:<P>
<INPUT TYPE="text" NAME="entry" VALUE="1/3">
<INPUT TYPE="button" VALUE=">Dollars and Cents">
onClick="this.form.result.value=dollarize(this.form.entry.value)">
<INPUT TYPE="text" NAME="result">
</FORM>
</BODY>
</HTML>
```

This routine may seem like a great deal of work, but it's essential if your application relies on floating-point values and specific formatting for all browsers.

You can also enter floating-point numbers with exponents. An exponent is signified by the letter "e" (upper- or lowercase), followed by a sign (+ or -) and the exponent value. Here are examples of floating-point values expressed as exponents:

```
1e6 // 1,000,000 (the "+" symbol is optional on positive exponents)
1e-4 // 0.0001 (plus some error further to the right of the decimal)
-4e-3 // -0.004
```

For values between 1e-5 and 1e15, JavaScript renders numbers without exponents (although you can force a number to display in exponential notation in IE5.5 and NN6). All other values outside these boundaries return with exponential notation in all browsers.

Hexadecimal and octal integers

JavaScript enables you to work with values in decimal (base-10), hexadecimal (base-16), and octal (base-8) formats. You have only a few rules to follow when dealing with any of these values.

Decimal values cannot begin with a leading 0. Therefore, if your page asks users to enter decimal values that begin with a 0, your script must strip those zeroes from the input string or use the number parsing global functions (described in the next section) before performing any math on the values.

Hexadecimal integer values are expressed with a leading 0x or 0X. (That's a zero, not the letter "o.") The A through F values can appear in upper- or lowercase, as you prefer. Here are some hex values:

```
0X2B
0X1a
0xcc
```

Don't confuse the hex values used in arithmetic with the hexadecimal values used in color property specifications for Web documents. Those values are expressed in a special *hexadecimal triplet* format, which begins with a crosshatch symbol followed by the three hex values bunched together (such as #c0c0c0).

Octal values are represented by a leading 0 followed by any digits between 0 and 7. Octal values consist only of integers.

You are free to mix and match base values in arithmetic expressions, but JavaScript renders all results in decimal form. For conversions to other number bases, you have to employ a user-defined function in your script. Listing 35-2, for example, is a function that converts any decimal value from 0 to 255 into a JavaScript hexadecimal value.

Listing 35-2: Decimal-to-Hexadecimal Converter Function

```
function toHex(dec) {
    hexChars = "0123456789ABCDEF"
    if (dec > 255) {
        return null
    }
    var i = dec % 16
```

```

    var j = (dec - i) / 16
    result = "0X"
    result += hexChars.charAt(j)
    result += hexChars.charAt(i)
    return result
}

```

The `toHex()` conversion function assumes that the value passed to the function is a decimal integer. If you simply need a hexadecimal representation of a number in string format, see the `toString()` method in Chapter 42.

Converting strings to numbers

What is missing so far from this discussion is a way to convert a number represented as a string to a number with which the JavaScript arithmetic operators can work. Before you get too concerned about this, be aware that most JavaScript operators and math methods gladly accept string representations of numbers and handle them without complaint. You will run into data type incompatibilities most frequently when trying to accomplish addition with the `+` operator (which is also the string concatenation operator). Also know that if you perform math operations on values retrieved from form text boxes, those object `value` properties are strings. Therefore, in many cases, you need to convert those values to values of the number type for math operations.

Conversion to numbers requires one of two JavaScript functions:

```

parseInt(string [,radix])
parseFloat(string [,radix])

```

These functions, inspired by the Java language. The term *parsing* has many implied meanings in programming. One meaning is the same as *extracting*. The `parseInt()` function returns whatever integer value it can extract from the string passed to it; the `parseFloat()` function returns the floating-point number that can be extracted from the string. Here are some examples and their resulting values:

```

parseInt("42")           // result = 42
parseInt("42.33")       // result = 42
parseFloat("42.33")     // result = 42.33
parseFloat("42")        // result = 42
parseFloat("fred")      // result = NaN

```

Because the `parseFloat()` function can also work with an integer and return an integer value, you may prefer using this function in scripts that have to deal with either kind of number, depending on the string entered into a text field by a user.

An optional second parameter to both functions enables you to specify the base of the number represented by the string. This comes in handy particularly when you need a decimal number from a string that starts with one or more zeros. Normally, the leading zero indicates an octal value. But if you force the conversion to recognize the string value as a decimal, it is converted the way you expect:

```

parseInt("010")          // result = 8
parseInt("010",10)      // result = 10
parseInt("F2")           // result = NaN
parseInt("F2", 16)      // result = 242

```

Use these functions wherever you need the integer or floating-point value. For example:

```
var result = 3 + parseInt("3")    // result = 6
var ageVal = parseInt(document.forms[0].age.value)
```

The latter technique ensures that the string value of this property is converted to a number (although you should do more data validation — see Chapter 43 — before trying any math on a user-entered value).

Both the `parseInt()` and `parseFloat()` methods start working on the first character of a string and continue until there are no more numbers or decimal characters. That's why you can use them on strings — such as the one returned by the `navigator.appVersion` property (for example, 4.0 (compatible; MSIE 5.5; Windows95)) — to obtain just the leading, numeric part of the string. If the string does not begin with an acceptable character, the methods return `NaN` (not a number).

Converting numbers to strings

If you attempt to pass a numeric data type value to many of the string methods discussed in Chapter 34, JavaScript complains. Therefore, you should convert any number to a string before you, for example, find out how many digits make up a number.

There are several ways to force conversion from any numeric value to a string. The old-fashioned way is to precede the number with an empty string and the concatenation operator. For example, assume that a variable named `dollars` contains the integer value of 2500. To use the string object's `length` property (discussed later in this chapter) to find out how many digits the number has, use this construction:

```
("" + dollars).length    // result = 4
```

The parentheses force JavaScript to evaluate the concatenation before attempting to extract the `length` property.

A more elegant way is to use the `toString()` method. Construct such statements as you do to invoke any object's method. For example, to convert the `dollars` variable value to a string, use this statement:

```
dollars.toString()    // result = "2500"
```

This method has one added power in NN3+ and IE4+: You can specify a number base for the string representation of the number. Called the *radix*, the base number is added as a parameter to the method name. Here is an example of creating a numeric value for conversion to its hexadecimal equivalent as a string:

```
var x = 30
var y = x.toString(16)    // result = "1e"
```

Use a parameter of 2 for binary results and 8 for octal. The default is base 10. Be careful not to confuse these conversions with true numeric conversions. You cannot use results from the `toString()` method as numeric operands in other statements.

Finally, in IE5.5 and NN6, three additional methods of the `Number` object — `toExponential()`, `toFixed()`, and `toPrecision()` — return string versions of

numbers formatted according to the rules and parameters passed to the methods. I describe these in detail later in this chapter.

When a number isn't a number

In a couple of examples in the previous section, you probably noticed that the result of some operations was a value named `NaN`. That value is not a string but rather a special value that stands for Not a Number. For example, if you try to convert the string "joe" to an integer with `parseFloat()`, the function cannot possibly complete the operation. It reports back that the source string, when converted, is not a number.

When you design an application that requests user input or retrieves data from a server-side database, you cannot be guaranteed that a value you need to be numeric is, or can be converted to, a number. If that's the case, you need to see if the value is a number before performing some math operation on it. JavaScript provides a special global function, `isNaN()`, that enables you to test the "number-ness" of a value. The function returns `true` if the value is not a number and `false` if it is a number. For example, you can examine a form field that should be a number:

```
var ageEntry = parseInt(document.forms[0].age.value)
if (isNaN(ageEntry)) {
    alert("Try entering your age again.")
}
```

**Note**

`NaN` and `isNaN()` are implemented in Navigator 2 only on UNIX versions. You can find these terms on all OS platforms of NN3+ and IE4+.

Math Object

Whenever you need to perform math that is more demanding than simple arithmetic, look through the list of `Math` object methods for the solution.

Syntax

Accessing `Math` object properties and methods:

```
Math.property
Math.method(value [, value])
```

About this object

In addition to the typical arithmetic operations (covered in detail in Chapter 40), JavaScript includes more advanced mathematical powers that you can access in a way that may seem odd to you if you have not programmed in true object-oriented environments before. Although most arithmetic takes place on the fly (such as `var result = 2 + 2`), the rest requires use of the JavaScript internal `Math` object (with a capital "M"). The `Math` object brings with it several properties (which behave like some other languages' constants) and many methods (which behave like some other languages' math functions).

The way you use the `Math` object in statements is the same way you use any JavaScript object: You create a reference beginning with the `Math` object's name, a period, and the name of the property or method you need:

```
Math.property | method([parameter]. . . [,parameter])
```

Property references return the built-in values (things such as pi). Method references require one or more values to be sent as parameters of the method. Every method returns a result.

Properties

JavaScript `Math` object properties represent a number of valuable constant values in math. Table 35-1 shows you those methods and their values as displayed to 16 decimal places.

Table 35-1 JavaScript Math Properties

<i>Property</i>	<i>Value</i>	<i>Description</i>
<code>Math.E</code>	2.718281828459045091	Euler's constant
<code>Math.LN2</code>	0.6931471805599452862	Natural log of 2
<code>Math.LN10</code>	2.302585092994045901	Natural log of 10
<code>Math.LOG2E</code>	1.442695040888963387	Log base-2 of E
<code>Math.LOG10E</code>	0.4342944819032518167	Log base-10 of E
<code>Math.PI</code>	3.141592653589793116	π
<code>Math.SQRT1_2</code>	0.7071067811865475727	Square root of 0.5
<code>Math.SQRT2</code>	1.414213562373095145	Square root of 2

Because these property expressions return their constant values, you use them in your regular arithmetic expressions. For example, to obtain the circumference of a circle whose diameter is in variable `d`, employ this statement:

```
circumference = d * Math.PI
```

Perhaps the most common mistakes scripters make with these properties are failing to capitalize the `Math` object name and observing the case-sensitivity of property names.

Methods

Methods make up the balance of JavaScript `Math` object powers. With the exception of the `Math.random()` method, all `Math` object methods take one or more values as parameters. Typical trigonometric methods operate on the single values passed as parameters; others determine which of the numbers passed along are the highest or lowest of the group. The `Math.random()` method takes no parameters but returns a randomized, floating-point value between 0 and 1 (note that the method does not work on Windows or Macintosh versions of

Navigator 2). Table 35-2 lists all the `Math` object methods with their syntax and descriptions of the values they return.

Table 35-2 Math Object Methods

Method Syntax	Returns
<code>Math.abs(val)</code>	Absolute value of <i>val</i>
<code>Math.acos(val)</code>	Arc cosine (in radians) of <i>val</i>
<code>Math.asin(val)</code>	Arc sine (in radians) of <i>val</i>
<code>Math.atan(val)</code>	Arc tangent (in radians) of <i>val</i>
<code>Math.atan2(val1, val2)</code>	Angle of polar coordinates <i>x</i> and <i>y</i>
<code>Math.ceil(val)</code>	Next integer greater than or equal to <i>val</i>
<code>Math.cos(val)</code>	Cosine of <i>val</i>
<code>Math.exp(val)</code>	Euler's constant to the power of <i>val</i>
<code>Math.floor(val)</code>	Next integer less than or equal to <i>val</i>
<code>Math.log(val)</code>	Natural logarithm (base <i>e</i>) of <i>val</i>
<code>Math.max(val1, val2)</code>	The greater of <i>val1</i> or <i>val2</i>
<code>Math.min(val1, val2)</code>	The lesser of <i>val1</i> or <i>val2</i>
<code>Math.pow(val1, val2)</code>	<i>val1</i> to the <i>val2</i> power
<code>Math.random()</code>	Random number between 0 and 1
<code>Math.round(val)</code>	<i>N</i> +1 when <i>val</i> \geq <i>N</i> .5; otherwise <i>N</i>
<code>Math.sin(val)</code>	Sine (in radians) of <i>val</i>
<code>Math.sqrt(val)</code>	Square root of <i>val</i>
<code>Math.tan(val)</code>	Tangent (in radians) of <i>val</i>

HTML is not exactly a graphic artist's dream environment, so using trig functions to obtain a series of values for HTML-generated charting is not a hot JavaScript prospect. Only with the advent of positionable elements have scripters been able to apply their knowledge of using these functions to define fancy trajectories for flying elements. For scripters who are not trained in programming, math is often a major stumbling block. But as you've seen so far, you can accomplish a great deal with JavaScript by using simple arithmetic and a little bit of logic—leaving the heavy-duty math for those who love it.

Creating random numbers

The `Math.random()` method returns a floating-point value between 0 and 1. If you design a script to act like a card game, you need random integers between 1 and 52; for dice, the range is 1 to 6 per die. To generate a random integer between zero and any top value, use the following formula:

```
Math.floor(Math.random() * n)
```

Here, n is the top number. To generate random numbers between a different range, use this formula:

```
Math.floor(Math.random() * m) + m
```

Here, m is the lowest possible integer value of the range and n equals the top number of the range. For the dice game, the formula for each die is

```
newDieValue = Math.floor(Math.random() * 6) + 1
```

Math object shortcut

In Chapter 39, you see details about a JavaScript construction that enables you to simplify the way you address multiple `Math` object properties and methods in statements. The trick is to use the `with` statement.

In a nutshell, the `with` statement tells JavaScript that the next group of statements (inside the braces) refers to a particular object. In the case of the `Math` object, the basic construction looks like this:

```
with (Math) {
    //statements
}
```

For all intervening statements, you can omit the specific references to the `Math` object. Compare the long reference way of calculating the area of a circle (with a radius of six units)

```
result = Math.pow(6,2) * Math.PI
```

to the shortcut reference way:

```
with (Math) {
    result = pow(6,2) * PI
}
```

Though the latter occupies more lines of code, the object references are shorter and more natural when reading the code. For a longer series of calculations involving `Math` object properties and methods, the `with` construction saves keystrokes and reduces the likelihood of a case-sensitive mistake with the object name in a reference. You can also include other full-object references within the `with` construction; JavaScript attempts to attach the object name only to those references lacking an object name. On the downside, the `with` construction is not particularly efficient in JavaScript because it must perform a lot of internal tracking in order to work.

Number Object

<i>Properties</i>	<i>Methods</i>
constructor	toExponential()

About this object

The `Number` object is rarely used because (for the most part) JavaScript satisfies day-to-day numeric needs with a plain number value. But the `Number` object contains some information and power of value to serious programmers.

First on the docket are properties that define the ranges for numbers in the language. The largest number (in both Navigator and Internet Explorer) is 1.79E+308; the smallest number is 2.22E-308. Any number larger than the maximum is `POSITIVE_INFINITY`; any number smaller than the minimum is `NEGATIVE_INFINITY`. Rarely will you accidentally encounter these values.

More to the point of a JavaScript object, however, is the `prototype` property. In Chapter 34, you see how to add a method to a `string` object's `prototype` such that every newly created object contains that method. The same goes for the `Number.prototype` property. If you have a need to add common functionality to every number object, this is where to do it. This prototype facility is unique to full-fledged number objects and does not apply to plain number values. For experienced programmers who care about such matters, JavaScript number objects and values are defined internally as IEEE double-precision 64-bit values.

Properties

constructor

See `string.constructor` (Chapter 34).

`MAX_VALUE`

`MIN_VALUE`

NEGATIVE_INFINITY POSITIVE_INFINITY

Value: Number

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

The `Number.MAX_VALUE` and `Number.MIN_VALUE` properties belong to the static `Number` object. They represent constants for the largest and smallest possible positive numbers that JavaScript (and ECMAScript) can work with. Their actual values are $1.7976931348623157 * 10^{308}$, and $5 * 10^{-324}$, respectively.

A number that falls outside the range of allowable numbers is equal to the constant `Number.POSITIVE_INFINITY` or `Number.NEGATIVE_INFINITY`.

Example on the CD-ROM

Related Items: `NaN` property; `isNaN()` global function.

NaN

Value: NaN

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

The `NaN` property is a constant that JavaScript uses to report when a number-related function or method attempts to work on a value other than a number or the result is something other than a number. You encounter the `NaN` value most commonly as the result of the `parseInt()` and `parseFloat()` functions whenever a string undergoing conversion to a number lacks a numeral as the first character. Use the `isNaN()` global function to see if a value is an `NaN` value.

Example

See the discussion of the `isNaN()` function in Chapter 42.

Related Item: `isNaN()` global function.

prototype

See `String.prototype` (Chapter 34).

Methods

`number.toExponential(fractionDigits)`

`number.toFixed(fractionDigits)`

`number.toPrecision(precisionDigits)`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

A recent addition to the ECMA language—and thus to the JavaScript-enabled browsers—are three `Number` object methods that let scripts control the formatting of numbers for display as string text. Each method has a unique purpose, but they all return strings. You should perform all math operations as unformatted number objects because the values have the most precision. Only after you are ready to display the results should you use one of these methods to convert the number to a string for display as body text or assignment to a text field.

The `toExponential()` method forces a number to display in exponential notation, even if the number is in the range in which JavaScript normally uses standard notation. The parameter is an integer specifying how many digits to the right of the decimal should be returned. All digits to the right of the decimal are returned, even if they are zero. For example, if a variable contains the numeric value 345, applying `toExponential(3)` to that value yields `3.450e+2`, which is JavaScript's exponential notation for 3.45×10^2 .

Use the `toFixed()` method when you want to format a number with a specific number of digits to the right of the decimal. This is the method you use, for instance, to display the results of a financial calculation in units and hundredths of units (for example, dollars and cents). The parameter to the method is an integer indicating the number of digits to be displayed to the right of the decimal. If the number being formatted has more numbers to the right of the decimal than the number of digits specified by the parameter, the method rounds the rightmost visible digit—but only with respect to the unrounded value of the next digit. For example, the value `123.455` fixed to two digits to the right of the decimal is rounded up to `123.46`. But if the starting value is `123.4549`, the method ignores the 9 and sees that the 4 to the right of the 5 should be rounded down; therefore, the result is `123.45`. Do not consider the `toFixed()` method to be an accurate rounder of numbers; however, it does a satisfactory job in most cases.

The final method is `toPrecision()`, which enables you to define how many total digits (including digits to the left and right of the decimal) to display of a number. In other words, you define the precision of a number. The following list demonstrates the results of several parameter values signifying a variety of precisions:

```
var num = 123.45
num.toPrecision(1) // result = 1e+2
num.toPrecision(2) // result = 1.2e+2
num.toPrecision(3) // result = 123
```

```
num.toPrecision(4) // result = 123.5
num.toPrecision(5) // result = 123.45
num.toPrecision(6) // result = 123.450
```

Notice that the same kind of rounding can occur with `toPrecision()` as it does for `toFixed()`.

Example on the CD-ROM

Related Item: Math object.

`number.toLocaleString()`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

According to the ECMA Edition 3 standard, browsers have some leeway in determining exactly how the `toLocaleString()` method should return a string value that conforms with the language standard of the client system or browser. IE5.5 appears to return the same value as the `toFixed(2)` method.

Related Items: `number.toFixed()`, `number.toString()` methods.

`number.toString([radix])`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

The `number.toString()` method returns a string value version of the current number. The default `radix` parameter (10) converts the value to base-10 notation if the original number isn't already of that type. Or you can specify other number bases (for example, 2 for binary, 16 for hexadecimal) to convert the original number to the other base—as a string, not a number, for further calculation.

Example on the CD-ROM

Related Item: `toLocaleString()` method.

`number.valueOf()`

See `string.valueOf()` (Chapter 34).

Boolean Object

<i>Properties</i>	<i>Methods</i>
constructor	toString()
prototype	valueOf()

Syntax

Creating a Boolean object:

```
var val = new Boolean(BooleanValue)
```

Accessing Boolean object properties:

```
BooleanObject.property | method
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

About this object

You work with Boolean values a lot in JavaScript — especially as the result of conditional tests. Just as string values benefit from association with string objects and their properties and methods, so, too, do Boolean values receive aid from the Boolean object. For example, when you display a Boolean value in a text box, the "true" or "false" string is provided by the Boolean object's `toString()` method so you don't have to invoke it directly.

The only time you need to even think about a Boolean object is if you wish to attach some property or method to Boolean objects that you create with the new `Boolean()` constructor. Parameter values for the constructor include the string versions of the values, numbers (0 for false; any other integer for true), and expressions that evaluate to a Boolean value. Any such new Boolean object is imbued with the new properties or methods you add to the prototype property of the core Boolean object.

For details about the properties and methods of the Boolean object, see the corresponding listings for the String object in Chapter 34.

36

CHAPTER

The Date Object

Perhaps the most untapped power of JavaScript is its date and time handling. Scripters passed over the `Date` object with good cause in the early days of JavaScript, because in earlier versions of scriptable browsers, significant bugs and platform-specific anomalies made date and time programming hazardous without significant testing. Even with the improved bug situation, working with dates requires a working knowledge of the world's time zones and their relationships with the standard reference point, known as Greenwich Mean Time (GMT) or Coordinated Universal Time (abbreviated UTC).

Now that date- and time-handling has improved in the latest browsers, I hope more scripters look into incorporating these kinds of calculations into their pages. In Chapter 54, for example, I show you an application that lets your Web site highlight the areas that have been updated since each visitor's last surf ride through your pages — an application that relies heavily on date arithmetic and time zone conversion.

Before getting to the JavaScript part of date discussions, however, the chapter summarizes key facts about time zones and their impact on scripting date and time on a browser. If you're not sure what GMT and UTC mean, the following section is for you.

Time Zones and GMT

By international agreement, the world is divided into distinct time zones that allow the inhabitants of each zone to say with confidence that when the Sun appears directly overhead, it is roughly noon, squarely in the middle of the day. The current time in the zone is what we set our clocks to — the local time.

That's fine when your entire existence and scope of life go no further than the width of your own time zone. But with instant communication among all parts of the world, your scope reaches well beyond local time. Periodically you must be aware of the local time in other zones. After all, if you live in New York, you don't want to wake up someone in Los Angeles before dawn with a phone call from your office.

Note

For the rest of this section, I speak of the Sun "moving" as if Earth were the center of the solar system. I do so for the convenience of our daily perception of the Sun arcing

In This Chapter

Working with date and time values in JavaScript

Performing date calculations

Validating date entry form fields

across what appears to us as a stationary sky. In point of fact, I believe Copernicus's theories, so delete that e-mail you were about to send me.

From the point of view of the time zone over which the Sun is positioned at any given instant, all time zones to the east have already had their noon, so it is later in the day for them — one hour later per time zone (except for those few time zones offset by fractions of an hour). That's why when U.S. television networks broadcast simultaneously to the eastern and central time zones, the announced schedule for a program is "10 eastern, 9 central."

Many international businesses must coordinate time schedules of far-flung events. Doing so and taking into account the numerous time zone differences (not to mention seasonal national variations, such as daylight saving time) would be a nightmare. To help everyone out, a standard reference point was devised: the time zone running through the celestial observatory at Greenwich (pronounced GREN-itch), England. This time zone is called Greenwich Mean Time, or GMT for short. The "mean" part comes from the fact that on the exact opposite side of the globe (through the Pacific Ocean) is the international date line, another world standard that decrees where the first instance of the next calendar day appears on the planet. Thus, GMT is located at the middle, or mean, of the full circuit of the day. Not that many years ago, GMT was given another abbreviation that is not based on any one language of the planet. The abbreviation is UTC (pronounced as its letters: yu-tee-see), and the English version is Coordinated Universal Time. Whenever you see UTC, it is for all practical purposes the same as GMT.

If your personal computer's system clock is set correctly, the machine ticks away in GMT time. But because you set your local time zone in the appropriate control panel, all file time stamps and clock displays are in your local time. The machine knows what the offset time is between your local time and GMT. For daylight saving time, you may have to check a preference setting so that the offset is adjusted accordingly; in Windows 95 and later, the operating system knows when the change-over occurs and prompts you if changing the offset is okay. In any case, if you travel across time zones with a laptop, you should change the computer's time zone setting, not its clock.

JavaScript's inner handling of date and time works a lot like the PC clock (on which your programs rely). Date values that you generate in a script are stored internally in GMT time; however, almost all the displays and extracted values are in the local time of the visitor (not the Web site server). And remember that the date values are created on the visitor's machine by virtue of your script's generating that value — you don't send "living" date objects to the client from the server. This concept is perhaps the most difficult to grasp as you work with JavaScript date and time.

Whenever you program time and date in JavaScript for a public Web page, you must take the worldview. This view requires knowing that the visitor's computer settings determine the accuracy of the conversion between GMT and local time. You'll also have to do some testing by changing your PC's clock to times in other parts of the world and making believe you are temporarily in those remote locations, which isn't always easy to do. It reminds me of the time I was visiting Sydney, Australia. I was turning in for the night and switched on the television in the hotel. This hotel received a live satellite relay of a long-running U.S. television program,

Today. The program broadcast from New York was for the morning of the same day I was just finishing in Sydney. Yes, this time zone stuff can make your head hurt.

The Date Object

Like a handful of other objects in JavaScript and the document object models, there is a distinction between the single, static `Date` object that exists in every window (or frame) and a date object that contains a specific date and time. The static `Date` object (uppercase “D”) is used in only a few cases: Primarily to create a new instance of a date and to invoke a couple of methods that the `Date` object offers for the sake of some generic conversions.

Most of your date and time work, however, is with instances of the `Date` object. These instances are referred to generically as date objects (lowercase “d”). Each date object is a snapshot of an exact millisecond in time, whether it be for the instant at which you generate the object or for a specific time in the past or future you need for calculations. If you need to have a live clock ticking away, your scripts will repeatedly create new date objects to grab up-to-the-millisecond snapshots of your computer’s clock. To show the time on the page, extract the hours, minutes, and seconds from the snapshot date object, and then display the values as you like (for example, a digital readout, a graphical bar chart, and so on). By and large, it is the methods of a date object instance that your scripts invoke to read or modify individual components of a date object (for example, the month or hour).

Despite its name, every date object contains information about date and time. Therefore, even if you’re concerned only about the date part of an object’s data, time data is standing by as well. As you learn in a bit, the time element can catch you off-guard for some operations.

Creating a date object

The statement that asks JavaScript to make an object for your script uses the special object construction keyword `new`. The basic syntax for generating a new date object is as follows:

```
var dateObjectName = new Date([parameters])
```

The date object evaluates to an object data type rather than to some string or numeric value.

With the date object’s reference safely tucked away in the variable name, you access all date-oriented methods in the dot-syntax fashion with which you’re already familiar:

```
var result = dateObjectName.method()
```

With variables, such as `result`, your scripts perform calculations or displays of the date object’s data (some methods extract pieces of the date and time data from the object). If you then want to put some new value into the date object (such as adding a year to the date object), you assign the new value to the object by way of the method that lets you set the value:

```
dateObjectName.method(newValue)
```

This example doesn't look like the typical JavaScript assignment statement, which has an equals sign operator. But this statement is the way in which methods that set date object data work.

You cannot get very far into scripting dates without digging into time zone arithmetic. Although JavaScript may render the string equivalent of a date object in your local time zone, the internal storage is strictly GMT.

Even though you haven't yet seen details of a date object's methods, here is how you use two of them to add one year to today's date.

```
var oneDate = new Date()           // creates object with current GMT date
var theYear = oneDate.getYear()   // theYear is now storing the value 98
theYear = theYear + 1            // theYear now is 99
oneDate.setYear(theYear)         // new year value now in the object
```

At the end of this sequence, the `oneDate` object automatically adjusts all the other date components for the next year's date. The day of the week, for example, will be different, and JavaScript takes care of that for you, should you need to extract that data. With next year's data in the `oneDate` object, you may now want to extract that new date as a string value for display in a field on the page or submit it quietly to a CGI program on the server.

The issue of parameters for creating a new date object is a bit complex, mostly because of the flexibility that JavaScript offers the scripter. Recall that the job of the `new Date()` statement is to create a place in memory for all data that a date needs to store. What is missing from that task is the data—what date and time to enter into that memory spot. That's where the parameters come in.

If you leave the parameters empty, JavaScript takes that to mean you want today's date and the current time to be assigned to that new date object. JavaScript isn't any smarter, of course, than the setting of the internal clock of your page visitor's personal computer. If the clock isn't correct, JavaScript won't do any better of a job identifying the date and time.

**Note**

Remember that when you create a new date object, it contains the current time as well. The fact that the current date may include a time of 16:03:19 (in 24-hour time) may throw off things, such as days-between-dates calculations. Be careful.

To create a date object for a specific date or time, you have five ways to send values as a parameter to the `new Date()` constructor function:

```
new Date("Month dd, yyyy hh:mm:ss")
new Date("Month dd, yyyy")
new Date(yy,mm,dd,hh,mm,ss)
new Date(yy,mm,dd)
new Date(milliseconds)
```

The first four variations break down into two styles—a long string versus a comma-delimited list of data—each with optional time settings. If you omit time settings, they are set to 0 (midnight) in the date object for whatever date you entered. You cannot omit date values from the parameters—every date object must have a real date attached to it, whether you need it or not.

In the long string versions, the month is spelled out in full in English. No abbreviations are allowed. The rest of the data is filled with numbers representing the date, year, hours, minutes, and seconds, even if the order is different from your local way of indicating dates. For single-digit values, you can use either a one- or two-digit version (such as 4:05:00). Colons separate hours, minutes, and seconds.

The short versions contain a non-quoted list of integer values in the order indicated. JavaScript cannot know that a 30 means the date if you accidentally place it in the month slot.

You use the last version only when you have the millisecond value of a date and time available. This generally occurs after some math arithmetic (described later in this chapter), leaving you with a date and time in millisecond format. To convert that numeric value to a date object, use the new `Date()` constructor. From the new date object created, you can retrieve more convenient values about the date and time.

Native object properties and methods

Like the `String` and `Array` objects, the `Date` object features a small handful of properties and methods that all native JavaScript objects have in common. On the property side, the `Date` object in NN3+ and IE3/J2+ has a `prototype` property, which enables you to apply new properties and methods to every date object created in the current page. You can see examples of how this works in discussions of the prototype property for `String` and `Array` objects (Chapters 34 and 37, respectively). At the same time, every instance of a date object in IE4+ and NN6 has a `constructor` property that references the constructor function that generated the object.

Methods in common are `toString()` and `valueOf()` (both NN4+ and IE3/J2+). A date object has numerous methods that convert date object types to strings, most of which are more specific than the generic `toString()` one. The `valueOf()` method returns the millisecond integer that is stored for a particular date—the same value that you get with the more object-specific `getUTCMilliseconds()` method (see the following section).

Date methods

The bulk of a date object's methods are for reading parts of the date and time information and for changing the date and time stored in the object. These two categories of methods are easily identifiable because they all begin with the word “get” or “set.” Table 36-1 lists all of the methods of both the static `Date` object and, by inheritance, date object instances. The list is impressive—some would say frightening—but there are patterns you should readily observe. Most methods deal with a single component of a date and time value: year, month, date, and so forth. Each block of “get” and “set” methods also has two sets of methods: one for the local date and time conversion of the date stored in the object; one for the actual UTC date stored in the object. After you see the patterns, the list should be more manageable. Unless otherwise noted, a method has been part of the `Date` object since the first generation of scriptable browsers.

Table 36-1: Date Object Methods

<i>Method</i>	<i>Value Range</i>	<i>Description</i>
<code>dateObj.getFullYear()</code>	1970-...	Specified year (NN4+, IE3/J2+)
<code>dateObj.getYear()</code>	70-...	(See Text)
<code>dateObj.getMonth()</code>	0-11	Month within the year (January = 0)
<code>dateObj.getDate()</code>	1-31	Date within the month
<code>dateObj.getDay()</code>	0-6	Day of week (Sunday = 0)
<code>dateObj.getHours()</code>	0-23	Hour of the day in 24-hour time
<code>dateObj.getMinutes()</code>	0-59	Minute of the specified hour
<code>dateObj.getSeconds()</code>	0-59	Second within the specified minute
<code>dateObj.getTime()</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT
<code>dateObj.getMilliseconds()</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT (NN4+, IE3/J2+)
<code>dateObj.getUTCFullYear()</code>	1970-...	Specified UTC year (NN4+, IE3/J2+)
<code>dateObj.getUTCMonth()</code>	0-11	UTC month within the year (January = 0) (NN4+, IE3/J2+)
<code>dateObj.getUTCDate()</code>	1-31	UTC date within the month (NN4+, IE3/J2+)
<code>dateObj.getUTCDay()</code>	0-6	UTC day of week (Sunday = 0) (NN4+, IE3/J2+)
<code>dateObj.getUTCHours()</code>	0-23	UTC hour of the day in 24-hour time (NN4+, IE3/J2+)
<code>dateObj.getUTCMinutes()</code>	0-59	UTC minute of the specified hour (NN4+, IE3/J2+)
<code>dateObj.getUTCSeconds()</code>	0-59	UTC second within the specified minute (NN4+, IE3/J2+)
<code>dateObj.getUTCMilliseconds()</code>	0-...	UTC milliseconds since 1/1/70 00:00:00 GMT (NN4+, IE3/J2+)
<code>dateObj.setYear(val)</code>	1970-...	Be safe: always specify a four-digit year
<code>dateObj.setFullYear(val)</code>	1970-...	Specified year (NN4+, IE3/J2+)
<code>dateObj.setMonth(val)</code>	0-11	Month within the year (January = 0)
<code>dateObj.setDate(val)</code>	1-31	Date within the month
<code>dateObj.setDay(val)</code>	0-6	Day of week (Sunday = 0)
<code>dateObj.setHours(val)</code>	0-23	Hour of the day in 24-hour time
<code>dateObj.setMinutes(val)</code>	0-59	Minute of the specified hour

<code>dateObj.setSeconds(val)</code>	0-59	Second within the specified minute
<code>dateObj.setMilliseconds(val)</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT (NN4+, IE3/J2+)
<code>dateObj.setTime(val)</code>	0-...	Milliseconds since 1/1/70 00:00:00 GMT
<code>dateObj.setUTCFullYear(val)</code>	1970-...	Specified UTC year (NN4+, IE3/J2+)
<code>dateObj.setUTCMonth(val)</code>	0-11	UTC month within the year (January = 0) (NN4+, IE3/J2+)
<code>dateObj.setUTCDate(val)</code>	1-31	UTC date within the month (NN4+, IE3/J2+)
<code>dateObj.setUTCDay(val)</code>	0-6	UTC day of week (Sunday = 0) (NN4+, IE3/J2+)
<code>dateObj.setUTCHours(val)</code>	0-23	UTC hour of the day in 24-hour time (NN4+, IE3/J2+)
<code>dateObj.setUTCMinutes(val)</code>	0-59	UTC minute of the specified hour (NN4+, IE3/J2+)
<code>dateObj.setUTCSeconds(val)</code>	0-59	UTC second within the specified minute (NN4+, IE3/J2+)
<code>dateObj.setUTCMilliseconds(val)</code>	0-...	UTC milliseconds since 1/1/70 00:00:00 GMT (NN4+, IE3/J2+)
<code>dateObj.getTimezoneOffset()</code>	0-...	Minutes offset from GMT/UTC
<code>dateObj.toString()</code>		Date-only string in a format determined by browser (IE5.5)
<code>dateObj.toGMTString()</code>		Date/time string in universal format
<code>dateObj.toLocaleDateString()</code>		Date-only string in your system's localized format (NN6, IE5.5)
<code>dateObj.toLocaleString()</code>		Date/time string in your system's localized format
<code>dateObj.toLocaleTimeString()</code>		Time-only string in your system's localized format (NN6, IE5.5)
<code>dateObj.toString()</code>		Date/time string in a format determined by browser
<code>dateObj.toTimeString()</code>		Time-only string in a format determined by browser (IE5.5)
<code>dateObj.toUTCString()</code>		Date/time string in universal format (NN4+, IE3/J2+)
<code>Date.parse("dateString")</code>		Converts string date to milliseconds integer
<code>Date.UTC(date values)</code>		Converts GMT string date to milliseconds integer

Deciding between using the UTC or local versions of the methods depends on several factors. If the browsers you must support go back to the beginning, you will be stuck with the local versions in any case. But even for newer browsers, activities, such as calculating the number of days between dates or creating a countdown timer for a quiz, won't care which set you use, but you must use the same set for all calculations. If you start mixing local and UTC versions of date methods, you'll be destined to get wrong answers. Where the UTC versions come in most handy is when your date calculations must take into account the time zone of the client machine compared to some absolute in another time zone — calculating the time remaining to the chiming of Big Ben signifying the start of the New Year in London.

JavaScript maintains its date information in the form of a count of milliseconds (thousandths of a second) starting from January 1, 1970, in the GMT (UTC) time zone. Dates before that starting point are stored as negative values (but see the section on bugs and gremlins later in this chapter). Regardless of the country you are in or the date and time formats specified for your computer, the millisecond is the JavaScript universal measure of time. Any calculations that involve adding or subtracting times and dates should be performed in the millisecond values to ensure accuracy. Therefore, though you may never display the milliseconds value in a field or dialog box, your scripts will probably work with them from time to time in variables. To derive the millisecond equivalent for any date and time stored in a date object, use the `dateObj.getTime()` method, as in

```
var startDate = new Date()
var started = startDate.getTime()
```

Although the method has the word “time” in its name, the fact that the value is the total number of milliseconds from January 1, 1970, means the value also conveys a date.

Other date object get methods read a specific component of the date or time. You have to exercise some care here, because some values begin counting with 0 when you may not expect it. For example, January is month 0 in JavaScript's scheme; December is month 11. Hours, minutes, and seconds all begin with 0, which, in the end, is logical. Calendar dates, however, use the actual number that would show up on the wall calendar: The first day of the month is date value 1. For the twentieth century years, the year value is whatever the actual year number is, minus 1900. For 1996, that means the year value is 96. But for years before 1900 and after 1999, JavaScript uses a different formula, showing the full year value. This means you have to check whether a year value is less than 100 and add 1900 to it before displaying that year.

```
var today = new Date()
var thisYear = today.getFullYear()
if (thisYear < 100) {
    thisYear += 1900
}
```

This assumes, of course, you won't be working with years before A.D. 100. If your audience is strictly IE3/J2+ and NN4+, then use only the `getFullYear()` method, which returns the complete set of year digits from all ranges.

To adjust any one of the elements of a date value, use the corresponding set method in an assignment statement. If the new value forces the adjustment of other

elements, JavaScript takes care of that. For example, consider the following sequence and how some values are changed for us:

```
myBirthday = new Date("September 11, 2001")
result = myBirthday.getDay() // result = 2, a Tuesday
myBirthday.setYear(2002) // bump up to next year
result = myBirthday.getDay() // result = 3, a Wednesday
```

Because the same date in the following year is on a different day, JavaScript tracks that for you.

Accommodating time zones

Understanding the `dateObj.getTimezoneOffset()` method involves both your operating system's time control panel setting and an internationally recognized (in computerdom, anyway) format for representing dates and times. If you have ignored the control panel stuff about setting your local time zone, the values you get for this property may be off for most dates and times. In the eastern part of North America, for instance, the eastern standard time zone is five hours earlier than Greenwich Mean Time. With the `getTimezoneOffset()` method producing a value of minutes' difference between GMT and the PC's time zone, the five hours difference of eastern standard time is rendered as a value of 300 minutes. On the Windows platform, the value automatically changes to reflect changes in daylight saving time in the user's area (if applicable). Offsets to the east of GMT (to the date line) are expressed as negative values.

Dates as strings

When you generate a date object, JavaScript automatically applies the `toString()` method to the object if you attempt to display that date either in a page or alert box. The format of this string varies with browser and operating system platform. For example, in Navigator 4 for Windows 98, the string is in the following format:

```
Wed Oct 31 11:43:34 GMT-0800 (Pacific Standard Time) 2001
```

But in the same version for Macintosh, the string is

```
Wed Oct 31 11:43:34 GMT-0800 2001
```

Internet Explorer returns its own variations on the string. The point is not to rely on a specific format and character location of this string for the components of dates. Use the date object methods to read date object components.

JavaScript does, however, provide two methods that return the date object in more constant string formats. One, `dateObj.toGMTString()`, converts the date and time to the GMT equivalent on the way to the variable that you use to store the extracted data. Here is what such data looks like:

```
Wed, 1 Nov 2000 04:25:28 GMT
```

If you're not familiar with the workings of GMT and how such conversions can present unexpected dates, exercise great care in testing your application. Eight o'clock on a Friday evening in California in the winter is four o'clock on Saturday morning GMT.

If time zone conversions make your head hurt, you can use the second string method, `dateObj.toLocaleString()`. In Navigator 3 for North American Windows users, the returned value looks like this:

```
10/31/2000 20:25:28
```

Starting with IE5.5 and NN6, you can also have JavaScript convert a date object to just the date or time portions in a nicely formatted version. The best pair of methods for this are `toLocaleDateString()` and `toLocaleTimeString()`, because these methods return values that make the most sense to the user, based on the localization settings of the user's operating system and browser.

Friendly date formats for older browsers

If you don't have the luxury of writing only for IE5.5+ or NN6+, you can create your own formatting function to do the job for a wide range of browsers. Listing 36-1 demonstrates one way of creating this kind of string from a date object (in a form compatible with Navigator 2 and Internet Explorer 3 pseudo-arrays).

Listing 36-1: Creating a Friendly Date String

```
<HTML>
<HEAD>
<TITLE>Date String Maker</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function MakeArray(n) {
    this.length = n
    return this
}
monthNames = new MakeArray(12)
monthNames[1] = "January"
monthNames[2] = "February"
monthNames[3] = "March"
monthNames[4] = "April"
monthNames[5] = "May"
monthNames[6] = "June"
monthNames[7] = "July"
monthNames[8] = "August"
monthNames[9] = "September"
monthNames[10] = "October"
monthNames[11] = "November"
monthNames[12] = "December"

dayNames = new MakeArray(7)
dayNames[1] = "Sunday"
dayNames[2] = "Monday"
dayNames[3] = "Tuesday"
dayNames[4] = "Wednesday"
dayNames[5] = "Thursday"
dayNames[6] = "Friday"
dayNames[7] = "Saturday"
```

```

function customDateString(oneDate) {
    var theDay = dayNames[oneDate.getDay() + 1]
    var theMonth = monthNames[oneDate.getMonth() + 1]
    var theYear = oneDate.getYear()
    theYear += (theYear < 100) ? 1900 : 0
    return theDay + ", " + theMonth + " " + oneDate.getDate() + ", " + theYear
}
</SCRIPT>
</HEAD>

<BODY>
<H1> Welcome!</H1>
<SCRIPT LANGUAGE="JavaScript">
document.write(customDateString(new Date()))
</SCRIPT>

<HR>
</BODY>
</HTML>

```

Assuming the user has the PC's clock set correctly (a big assumption), the date appearing just below the opening headline is the current date—making it appear as though the document had been updated today. The downside to this approach (as opposed to the newer `toLocaleDateString()` method) is that international users are forced to view dates in the format you design, which may be different from their local custom.

More conversions

The last two methods shown in Listing 36-1 are methods of the static `Date` object. These utility methods convert dates from string or numeric forms into millisecond values of those dates. The primary beneficiary of these actions is the `dateObj.setTime()` method, which requires a millisecond measure of a date as a parameter. You use this method to throw an entirely different date into an existing date object.

`Date.parse()` accepts as a parameter date strings similar to the ones you've seen in this section, including the internationally approved version. `Date.UTC()`, on the other hand, requires the comma-delimited list of values (in proper order: `yy,mm,dd,hh,mm,ss`) in the GMT zone. The `Date.UTC()` method gives you a backward-compatible way to hard-code a GMT time (you can do the same in NN4+ and IE4+ via the UTC methods). The following is an example that creates a new date object for 6 p.m. on March 4, 2002, GMT in IE5/Windows:

```

var newObj = new Date(Date.UTC(2002,2,4,18,0,0))
result = newObj.toString() // result = "Mon, Mar 04 10:00:00 PST 2002"

```

The second statement returns a value in a local time zone, because all non-UTC methods automatically convert the GMT time stored in the object to the client's local time.

Date and time arithmetic

You may need to perform some math with dates for any number of reasons. Perhaps you need to calculate a date at some fixed number of days or weeks in the future or figure out the number of days between two dates. When calculations of these types are required, remember the *lingua franca* of JavaScript date values: milliseconds.

What you may need to do in your date-intensive scripts is establish some variable values representing the number of milliseconds for minutes, hours, days, or weeks, and then use those variables in your calculations. Here is an example that establishes some practical variable values, building on each other:

```
var oneMinute = 60 * 1000
var oneHour = oneMinute * 60
var oneDay = oneHour * 24
var oneWeek = oneDay * 7
```

With these values established in a script, I can use one to calculate the date one week from today:

```
var targetDate = new Date()
var dateInMs = targetDate.getTime()
dateInMs += oneWeek
targetDate.setTime(dateInMs)
```

Another example uses components of a date object to assist in deciding what kind of greeting message to place in a document, based on the local time of the user's PC clock. Listing 36-2 adds to the scripting from Listing 36-1, bringing some quasi-intelligence to the proceedings. Again, this script uses the older array creation mechanism to be compatible with Navigator 2 and Internet Explorer 3.

Listing 36-2: A Dynamic Welcome Message

```
<HTML>
<HEAD>
<TITLE>Date String Maker</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function MakeArray(n) {
    this.length = n
    return this
}
monthNames = new MakeArray(12)
monthNames[1] = "January"
monthNames[2] = "February"
monthNames[3] = "March"
monthNames[4] = "April"
monthNames[5] = "May"
monthNames[6] = "June"
monthNames[7] = "July"
monthNames[8] = "August"
monthNames[9] = "September"
monthNames[10] = "October"
monthNames[11] = "November"
monthNames[12] = "December"
```

```

dayNames = new MakeArray(7)
dayNames[1] = "Sunday"
dayNames[2] = "Monday"
dayNames[3] = "Tuesday"
dayNames[4] = "Wednesday"
dayNames[5] = "Thursday"
dayNames[6] = "Friday"
dayNames[7] = "Saturday"

function customDateString(oneDate) {
    var theDay = dayNames[oneDate.getDay() + 1]
    var theMonth = monthNames[oneDate.getMonth() + 1]
    var theYear = oneDate.getYear()
    theYear += (theYear < 100) ? 1900 : 0
    return theDay + ", " + theMonth + " " + oneDate.getDate() + ", " + theYear
}

function dayPart(oneDate) {
    var theHour = oneDate.getHours()
    if (theHour < 6 )
        return "wee hours"
    if (theHour < 12)
        return "morning"
    if (theHour < 18)
        return "afternoon"
    return "evening"
}
</SCRIPT>
</HEAD>

<BODY>
<H1> Welcome!</H1>
<SCRIPT LANGUAGE="JavaScript">
today = new Date()
var header = (customDateString(today)).italics()
header += "<BR>We hope you are enjoying the "
header += dayPart(today) + "."
document.write(header)
</SCRIPT>
<HR>
</BODY>
</HTML>

```

The script divides the day into four parts and presents a different greeting for each part of the day. The greeting that plays is based, simply enough, on the hour element of a date object representing the time the page is loaded into the browser. Because this greeting is embedded in the page, the greeting does not change no matter how long the user stays logged on to the page.

Counting the days...

You may find one or two more date arithmetic applications useful. One displays the number of shopping days left until Christmas (in the user's time zone); the other is a countdown timer to the start of the year 2100.

Listing 36-3 demonstrates how to calculate the number of days between the current day and some fixed date in the future. The assumption in this application is that all calculations take place in the user's time zone. The example shows the display of the number of shopping days before the next Christmas day (December 25). The basic operation entails converting the current date and the next December 25 to milliseconds, calculating the number of days represented by the difference in milliseconds. If you let the millisecond values represent the dates, JavaScript automatically takes care of leap years.

The only somewhat tricky part is setting the year of the next Christmas day correctly. You can't just slap the fixed date with the current year, because if the program is run on December 26, the year of the next Christmas must be incremented by one. That's why the constructor for the Christmas date object doesn't supply a fixed date as its parameters but, rather, sets individual components of the object.

Listing 36-3: How Many Days Until Christmas

```
<HTML>
<HEAD>
<TITLE>Christmas Countdown</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function getDaysUntilXmas() {
    var oneMinute = 60 * 1000
    var oneHour = oneMinute * 60
    var oneDay = oneHour * 24
    var today = new Date()
    var nextXmas = new Date()
    nextXmas.setMonth(11)
    nextXmas.setDate(25)
    if (today.getMonth() == 11 && today.getDate() > 25) {
        nextXmas.setFullYear(nextXmas.getFullYear() + 1)
    }
    var diff = nextXmas.getTime() - today.getTime()
    diff = Math.floor(diff/oneDay)
    return diff
}
</SCRIPT>
</HEAD>

<BODY>
<H1>
<SCRIPT LANGUAGE="JavaScript">
var header = "You have <I>" + getDaysUntilXmas() + "</I> "
header += "shopping days until Christmas."
document.write(header)
</SCRIPT>
</H1><HR>
</BODY>
</HTML>
```

The second variation on calculating the amount of time before a certain event takes time zones into account. For this demonstration, the page is supposed to display a countdown timer to the precise moment when the flame for the 2004 Summer Games in Athens is to be lit. That event takes place in a time zone that may be different from that of the page's viewer, so the countdown timer must calculate the time difference accordingly.

Listing 36-4 shows a simplified version that simply displays the ticking timer in a text field. The output, of course, could be customized in any number of ways, depending on the amount of dynamic HTML you want to employ on a page. The time of the lighting for this demo is set at 17:00 GMT on August 13, 2004 (the date is certainly accurate, but the officials may set a different time closer to the actual event).

Because this application is implemented as a live ticking clock, the code starts by setting some global variables that should be calculated only once so that the function that gets invoked repeatedly has a minimum of calculating to do (to be more efficient). The `Date.UTC()` method provides the target time and date in standard time. The `getTimeUntil()` function accepts a millisecond value (as provided by the `targetDate` variable) and calculates the difference between the target date and the actual internal millisecond value of the client's PC clock.

The core of the `getCountDown()` function peels off the number of whole days, hours, minutes, and seconds from the total number of milliseconds difference between now and the target date. Notice that each chunk is subtracted from the total so that the next smaller chunk can be calculated from the leftover milliseconds.

One extra touch on this page is that users of Windows operating systems have a display of the local date and time of the actual event. The Mac is excluded because it does not provide accurate daylight saving time adjustments for local dates. Some UNIX flavors may do the right thing, but they were not tested for this example.

Listing 36-4: Summer Games Countdown

```
<HTML>
<HEAD>
<TITLE>Summer Games Countdown</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// globals -- calculate only once
// set target date to 1700GMT on August 13, 2004
var targetDate = Date.UTC(2004, 7, 13, 17, 0, 0, 0)
var oneMinute = 60 * 1000
var oneHour = oneMinute * 60
var oneDay = oneHour * 24

function getTimeUntil(targetMS) {
    var today = new Date()
    var diff = targetMS - today.valueOf()
    return Math.floor(diff)
}

function getCountDown() {
    var ms = getTimeUntil(targetDate)
    var output = ""
    var days, hrs, mins, secs
    if (ms >= 0) {
```

Continued

Listing 36-4 (continued)

```

        days = Math.floor(ms/oneDay)
        ms -= oneDay * days
        hrs = Math.floor(ms/oneHour)
        ms -= oneHour * hrs
        mins = Math.floor(ms/oneMinute)
        ms -= oneMinute * mins
        secs = Math.floor(ms/1000)
        output += days + " Days, " +
            hrs + " Hours, " +
            mins + " Minutes, " +
            secs + " Seconds"
    } else {
        output += "The time has passed."
    }
    return output
}
function updateCountDown() {
    document.forms[0].timer.value = getCountDown()
    setTimeout("updateCountDown()", 1000)
}
</SCRIPT>
</HEAD>

<BODY onLoad="updateCountDown()">
<H1>Athens Games Torch Lighting Countdown</H1>
<P>

Date bugs and gremlins

Each new browser generation improves the stability and reliability of scripted date objects. Unfortunately, Navigator 2 has enough bugs and crash problems across many platforms to make scripting complex world-time applications for this browser impossible. The Macintosh version also has bugs that throw off dates by as much as a full day. I recommend avoiding NN2 on all platforms for serious date and time scripting.

The situation is much improved for NN3. Still, some bugs persist. One bug in particular affects Macintosh versions of NN3. Whenever you create a new date object with daylight saving time engaged in the Date and Time control panel, the browser automatically adds one hour to the object. See the time-based application in Chapter 54 for an example of how to counteract the effects of typical time bugs. Also afflicting the Macintosh in NN3 is a faulty calculation of the time zone offset for all time zones east of GMT. Instead of generating these values as negative numbers (getting lower and lower as you head east), the offset values increase continuously as you head west from Greenwich. While the Western Hemisphere is fine, the values continue to increase past the international date line, rather than switch over to the negative values.

Internet Explorer 3 isn't free of problems. It cannot handle dates before January 1, 1970 (GMT). Attempts to generate a date before that one result in that base date as the value. IE3 also completely miscalculates the time zone offset, following the erroneous pattern of Navigator 2. Even Navigators 3 and 4 have problems with historic dates. You are asking for trouble if the date extends earlier than January 1, A.D. 1. Internet Explorer 4, on the other hand, appears to sail very well into ancient history.

You should be aware of one more discrepancy between Mac and Windows versions of Navigator through Version 4. In Windows, if you generate a date object for a date in another part of the year, the browser sets the time zone offset for that object according to the time zone setting for that time of year. On the Mac, the current setting of the control panel governs whether the normal or daylight saving time offset is applied to the date, regardless of the actual date within the year. This discrepancy affects Navigator 3 and 4 and can throw off calculations from other parts of the year by one hour.

It may sound as though the road to Date object scripting is filled with land mines. While date and time scripting is far from hassle free, you can put it to good use with careful planning and a lot of testing.

Validating Date Entries in Forms

Given the bug horror stories in the previous section, you may wonder how you can ever perform data entry validation for dates in forms. The problem is not so much in the calculations as it is in the wide variety of acceptable date formats around the world. No matter how well you instruct users to enter dates in a particular format, many will follow their own habits and conventions. Moreover, how can you know whether an entry of 03/04/2002 is the North American March 4, 2002, or the European April 3, 2002? The answer: You can't.

My recommendation is to divide a date field into three components: month, day, and year. Let the user enter values into each field and validate each field individually for its valid range. Listing 36-5 shows an example of how this is done. The page includes a form that is to be validated before it is submitted. Each component field does its own range checking on the fly as the user enters values. But because this kind of validation can be defeated, the page includes one further check triggered by the form's `onSubmit` event handler. If any field is out of whack, the form submission is canceled.

Listing 36-5: Date Validation in a Form

The page shows the three entry fields as well as a field that is normally hidden on a form to be submitted to a CGI program. On the server end, the CGI program responds only to the hidden field with the complete date, which is in a format for entry into, for example, an Informix database.

Not every date entry validation must be divided in this way. For example, an intranet application can be more demanding in the way users are to enter data. Therefore, you can have a single field for date entry, but the parsing required for such a validation is quite different from that shown in Listing 36-5. See Chapter 43 for an example of such a one-field date validation routine.

37

CHAPTER

The Array Object

An array is the sole JavaScript data structure provided for storing and manipulating ordered collections of data. But unlike some other programming languages, JavaScript's arrays are very forgiving as to the kind of data you store in each cell or entry of the array. This allows, for example, an array of arrays, providing the equivalent of multidimensional arrays customized to the kind of data your application needs.

If you have not done a lot of programming in the past, the notion of arrays may seem like an advanced topic. But if you ignore their capabilities, you set yourself up for a harder job when implementing many kinds of tasks. Whenever I approach a script, one of my first thoughts is about the data being controlled by the application and whether handling it as an array will offer some shortcuts for creating the document and handling interactivity with the user.

I hope that by the end of this chapter, you will not only be familiar with the properties and methods of JavaScript arrays, but you will begin to look for ways to make arrays work for you.

Structured Data

In programming, an *array* is defined as an ordered collection of data. You can best visualize an array as a table, not much different from a spreadsheet. In JavaScript, arrays are limited to a table holding one column of data, with as many rows as needed to hold your data. As you have seen in many chapters in Part III, a JavaScript-enabled browser creates a number of internal arrays for the objects in your HTML documents and browser properties. For example, if your document contains five links, the browser maintains a table of those links. You access them by number (with 0 being the first link) in the array syntax: the array name is followed by the index number in square brackets, as in `document.links[0]`, which represents the first link in the document.

For many JavaScript applications, you will want to use an array as an organized warehouse for data that users of your page access, depending on their interaction with form elements. In the application shown in Chapter 50, for example, I demonstrate an extended version of this usage in a page that lets users search a small table of data for a match between the

In This Chapter

Working with ordered collections of data

Simulating multidimensional arrays

Manipulating information stored in an array

first three digits of their U.S. Social Security numbers and the state in which they registered with the agency. Arrays are the way JavaScript-enhanced pages can recreate the behavior of more sophisticated CGI programs on servers. When the collection of data you embed in the script is no larger than a typical `.gif` image file, the user won't experience significant delays in loading your page; yet he or she has the full power of your small database collection for instant searching without any calls back to the server. Such database-oriented arrays are important applications of JavaScript for what I call *serverless CGIs*.

As you design an application, look for clues as to potential application of arrays. If you have a number of objects or data points that interact with scripts the same way, you have a good candidate for array structures. For example, in every browser, with the exception of Internet Explorer 3, you can assign like names to every text field in a column of an order form. In that sequence, like-named objects are treated as elements of an array. To perform repetitive row calculations down an order form, your scripts can use array syntax to perform all the extensions within a handful of JavaScript statements, rather than perhaps dozens of statements hard-coded to each field name. Chapter 51 shows an example of this application.

You can also create arrays that behave like the Java hash table: a lookup table that gets you to the desired data point instantaneously if you know the name associated with the entry. If you can conceive your data in a table format, an array is in your future.

Creating an Empty Array

Arrays are treated in JavaScript like objects, but the extent to which your scripts can treat them as objects depends on whether you're using the first version of JavaScript (in Navigator 2 and Internet Explorer 3 with the Version 1 JScript DLL) or more recent versions (in Navigator 3 or later and Internet Explorer with JScript DLL Version 2 or later). For the sake of compatibility, I begin by showing you how to create arrays that work in all scriptable browsers.

You begin by defining an object *constructor* function that assigns a passed parameter integer value to the `length` property of the object:

```
function makeArray(n) {  
    this.length = n  
    return this  
}
```

Then, to actually initialize an array for your script, use the `new` keyword to construct the object for you while assigning the array object to a variable of your choice:

```
var myArray = new makeArray(n)
```

where *n* is the number of entries you anticipate for the array. This initialization does not make any array entries or create any placeholders. Such preconditioning of arrays is not necessary in JavaScript.

In one important aspect, an array created in this “old” manner does not exhibit an important characteristic of standard arrays. The `length` property here is artificial in that it does not change with the size of the array (true JavaScript arrays are completely dynamic, letting you add items at any time). The `length` value here is hardwired by assignment. You can always change the value manually, but it takes a great deal of scripted bookkeeping to manage that task.

Another point to remember about this property scheme is that the value assigned to `this.length` in the constructor actually occupies the first entry (index 0) of the array. Any data you want to add to an array should not overwrite that position in the array if you expect to use the `length` to help a repeat loop look through an array's contents.

What a full-fledged array object gains you is behavior more like that of the arrays you work with elsewhere in JavaScript. You don't need to define a constructor function, because it's built into the JavaScript object mechanism. Instead, you create a new array object, such as this:

```
var myArray = new Array()
```

An array object automatically has a `length` property (0 for an empty array). Most importantly, this `length` value does not occupy one of the array entries; the array is entirely for data.

Should you want to presize the array (for example, preload entries with `null` values), you can specify an initial size as a parameter to the constructor. For example, here is how to create a new array to hold information about a 500-item compact disc collection:

```
var myCDCollection = new Array(500)
```

Presizing an array does not give you any particular advantage, because you can assign a value to any slot in an array at any time: The `length` property adjusts itself accordingly. For instance, if you assign a value to `myCDCollection[700]`, the array object adjusts its `length` upward to meet that slot (with the count starting at 0):

```
myCDCollection [700] = "Gloria Estefan/Destiny"  
collectionSize = myCDCollection.length // result = 701
```

A true array object also features a number of methods and the capability to add prototype properties, described later in this chapter.

Populating an Array

Entering data into an array is as simple as creating a series of assignment statements, one for each element of the array. Listing 37-1 (not on the CD-ROM) assumes that you're using the newer style array object and that your goal is to generate an array containing a list of the nine planets of the solar system.

Listing 37-1: Generating and Populating a New Array

```
solarSys = new Array(9)  
solarSys[0] = "Mercury"  
solarSys[1] = "Venus"  
solarSys[2] = "Earth"  
solarSys[3] = "Mars"  
solarSys[4] = "Jupiter"  
solarSys[5] = "Saturn"  
solarSys[6] = "Uranus"  
solarSys[7] = "Neptune"  
solarSys[8] = "Pluto"
```

This way of populating a single array is a bit tedious when you're writing the code, but after the array is set, it makes accessing information collections as easy as any array reference:

```
onePlanet = solarSys[4]    // result = "Jupiter"
```

A more compact way to create an array is available if you know that the data will be in the desired order (as the preceding `solarSys` array). Instead of writing a series of assignment statements (as in Listing 37-1), you can create what is called a *dense array* by supplying the data as parameters to the `Array()` constructor:

```
solarSys = new Array("Mercury", "Venus", "Earth", "Mars", "Jupiter", "Saturn",
"Uranus", "Neptune", "Pluto")
```

The term “dense array” means that data is packed into the array, without gaps, starting at index position 0.

The example in Listing 37-1 shows what you may call a vertical collection of data. Each data point contains the same type of data as the other data points — the name of a planet — and the data points appear in the relative order of the planets from the Sun.

But not all data collections are vertical. You may, for instance, just want to create an array that holds various pieces of information about one planet. Earth is handy, so use some of its astronomical data to build a completely separate array of earthly info in Listing 37-2 (not on the CD-ROM).

Listing 37-2: Creating a “Horizontal” Array

```
earth = new Array()
earth.diameter = "7920 miles"
earth.distance = "93 million miles"
earth.year = "365.25 days"
earth.day = "24 hours"
earth.length    // result = 4
```

What you see in Listing 37-2 is an alternative way to populate an array. In a sense, you saw a preview of this approach for the creation of an array in the old style, where the `length` property name was assigned to its first entry. If you assign a value to a property name that has not yet been assigned for the array, JavaScript is smart enough to append a new property entry for that value.

In an important change from the old style of array construction, the way you define an array entry affects how you access that information later. For example, when you populate an array based on numeric index values (Listing 37-1), you can retrieve those array entries only via references that include the index values. Conversely, if you define array entries by property name (as in Listing 37-2), you cannot access those values via the numeric index way. In Navigator 2, for instance, the array assignments of Listing 37-2 can be retrieved by their corresponding index values:

```
earth.diameter    // result = "7920 miles"
earth["diameter"] // result = "7920 miles"
earth[0]          // result = "7920 miles"
```

In Navigator 3 or 4, however, because these entries are defined as named properties, they must be retrieved as properties, not as numeric index values:

```
earth.diameter           // result = "7920 miles"
earth["diameter"]       // result = "7920 miles"
earth[0]                 // result = null
```

The impact here on your scripts is that you need to anticipate how you expect to retrieve data from your array. If an indexed repeat loop is in the forecast, populate the array with index values (as in Listing 37-1); if the property names are more important to you, then populate the array that way (as in Listing 37-2). Your choice of index value type for a single-column array is driven by the application, but you will want to focus on the named array entry style for creating what appear to be two-dimensional arrays.

JavaScript 1.2 Array Creation Enhancements

The JavaScript version in NN4+ and IE4+ provides one more way to create a dense array and also clears up a bug in the old way. A new, simpler way to create a dense array does not require the `Array` object constructor. Instead, JavaScript 1.2 (and later) accepts what is called *literal notation* to generate an array. To demonstrate the difference, the following statement is the regular dense array constructor that works with Navigator 3:

```
solarSys = new Array("Mercury","Venus","Earth","Mars","Jupiter","Saturn",
"Uranus","Neptune","Pluto")
```

While JavaScript 1.2+ fully accepts the preceding syntax, it also accepts the new literal notation:

```
solarSys = ["Mercury","Venus","Earth","Mars","Jupiter","Saturn",
"Uranus","Neptune","Pluto"]
```

The square brackets stand in for the call to the `Array` constructor. You have to judge which browser types your audience will be using before deploying this streamlined approach to array creation.

The bug fix has to do with how to treat the earlier dense array constructor if the scripter enters only the numeric value 1 as the parameter — `new Array(1)`. In NN3 and IE4, JavaScript erroneously creates an array of length 1, but that element is undefined. For NN4 (and inside a `<SCRIPT LANGUAGE="JavaScript1.2">` tag) and all later browsers (IE5+, NN6), the same statement creates that one-element array and places the value in that element.

Deleting Array Entries

You can always set the value of an array entry to `null` or an empty string to wipe out any data that used to occupy that space. But until the `delete` operator in NN4 and IE4, you could not completely remove the element.

Deleting an array element eliminates the index from the list of accessible index values but does not reduce the array's length, as in the following sequence of statements:

```
myArray.length // result: 5
delete myArray[2]
```

```
myArray.length    // result: 5
myArray[2]        // result: undefined
```

The process of deleting an array entry does not necessarily release memory occupied by that data. The JavaScript interpreter's internal garbage collection mechanism (beyond the reach of scripters) is supposed to take care of such activity. See the `delete` operator in Chapter 40 for further details.

Parallel Arrays

Using an array to hold data is frequently desirable so that a script can do a lookup to see if a particular value is in the array (perhaps verifying that a value typed into a text box by the user is permissible); however, even more valuable is if, upon finding a match, a script can look up some related information in another array. One way to accomplish this is with two or more parallel arrays: the same indexed slot of each array contains related information.

Consider the following three arrays:

```
var regionalOffices = new Array("New York", "Chicago", "Houston", "Portland")
var regionalManagers = new Array("Shirley Smith", "Todd Gaston", "Leslie Jones",
    "Harold Zoot")
var regOfficeQuotas = new Array(300000, 250000, 350000, 225000)
```

The assumption for these statements is that Shirley Smith is the regional manager out of the New York office, and her office's quota is 300,000. This represents the data that is included with the document, perhaps retrieved by a CGI program on the server that gets the latest data from a SQL database and embeds the data in the form of array constructors. Listing 37-3 shows how this data appears in a simple page that looks up the manager name and quota values for whichever office is chosen in the `SELECT` element. The order of the items in the list of `SELECT` is not accidental: The order is identical to the order of the array for the convenience of the lookup script.

Lookup action in Listing 37-3 is performed by the `getData()` function. Because the index values of the options inside the `SELECT` element match those of the parallel arrays index values, the `selectedIndex` property of the `SELECT` element makes a convenient way to get directly at the corresponding data in other arrays.

Listing 37-3: A Simple Parallel Array Lookup

```
<HTML>
<HEAD>
<TITLE>Parallel Array Lookup</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// the data
var regionalOffices = new Array("New York", "Chicago", "Houston", "Portland")
var regionalManagers = new Array("Shirley Smith", "Todd Gaston", "Leslie Jones",
    "Harold Zoot")
var regOfficeQuotas = new Array(300000, 250000, 350000, 225000)
// do the lookup into parallel arrays
function getData(form) {
    var i = form.offices.selectedIndex
    form.manager.value = regionalManagers[i]
    form.quota.value = regOfficeQuotas[i]
```

```

}
</SCRIPT>
</HEAD>

<BODY onLoad="getData(document.officeData)">
<H1>Parallel Array Lookup</H1>
<HR>
<FORM NAME="officeData">
<P>
Select a regional office:
<SELECT NAME="offices" onChange="getData(this.form)">
  <OPTION>New York
  <OPTION>Chicago
  <OPTION>Houston
  <OPTION>Portland
</SELECT>
</P><P>
The manager is:
<INPUT TYPE="text" NAME="manager" SIZE=35>
<BR>
The office quota is:
<INPUT TYPE="text" NAME="quota" SIZE=8>
</P>
</FORM>
</BODY>
</HTML>

```

On the other hand, if the content to be looked up is typed into a text box by the user, you have to loop through one of the arrays to get the matching index. Listing 37-4 is a variation of Listing 37-3, but instead of the SELECT element, a text field asks users to type in the name of the region. Assuming that users will always spell the input correctly (an outrageous assumption), the version of `getData()` in Listing 37-4 performs actions that more closely resemble what you may think a “lookup” should be doing: looking for a match in one array, and displaying corresponding results from the parallel arrays. The `for` loop iterates through items in the `regionalOffices` array. An `if` condition compares all uppercase versions of both the input and each array entry. If there is a match, the `for` loop breaks, with the value of `i` still pointing to the matching index value. Outside the `for` loop, another `if` condition makes sure that the index value has not reached the length of the array, which means that no match is found. Only when the value of `i` points to one of the array entries does the script retrieve corresponding entries from the other two arrays.

Listing 37-4: A Looping Array Lookup

Multidimensional Arrays

An alternate to parallel arrays is the simulation of a multidimensional array. While it's true that JavaScript arrays are one-dimensional, you can create a one-dimensional array of other arrays or objects. A logical approach is to make an array of custom objects, because the objects easily allow for naming of object properties, making references to multidimensional array data more readable (custom objects are discussed at length in Chapter 41).

Using the same data from the examples of parallel arrays, the following statements define an object constructor for each “data record.” A new object is then assigned to each of four entries in the main array.

```
// custom object constructor
function officeRecord(city, manager, quota) {
    this.city = city
    this.manager = manager
    this.quota = quota
}

// create new main array
var regionalOffices = new Array()
// stuff main array entries with objects
regionalOffices[0] = new officeRecord("New York", "Shirley Smith", 300000)
regionalOffices[1] = new officeRecord("Chicago", "Todd Gaston", 250000)
regionalOffices[2] = new officeRecord("Houston", "Leslie Jones", 350000)
regionalOffices[3] = new officeRecord("Portland", "Harold Zoot", 225000)
```

The object constructor function (`officeRecord()`) assigns incoming parameter values to properties of the object. Therefore, to access one of the data points in the array, you use both array notations to get to the desired entry in the array and the name of the property for that entry's object:

```
var eastOfficeManager = regionalOffices[0].manager
```

You can also assign string index values for this kind of array, as in

```
regionalOffices["east"] = new officeRecord("New York", "Shirley Smith", 300000)
```

and access the data via the same index:

```
var eastOfficeManager = regionalOffices["east"].manager
```

But if you're more comfortable with the traditional multidimensional array (from your experience in other programming languages), you can also implement the above as an array of arrays with less code:

```
// create new main array
var regionalOffices = new Array()
// stuff main array entries with arrays
regionalOffices[0] = new Array("New York", "Shirley Smith", 300000)
regionalOffices[1] = new Array("Chicago", "Todd Gaston", 250000)
regionalOffices[2] = new Array("Houston", "Leslie Jones", 350000)
regionalOffices[3] = new Array("Portland", "Harold Zoot", 225000)
```

or, for the extreme of unreadable brevity with literal notation:

```
// create new main array
var regionalOffices = [ ["New York", "Shirley Smith", 300000],
                        ["Chicago", "Todd Gaston", 250000],
                        ["Houston", "Leslie Jones", 350000],
                        ["Portland", "Harold Zoot", 225000] ]
```

Accessing a single data point of an array of arrays requires a double array reference. For example, retrieving the manager's name for the Houston office requires the following syntax:

```
var HoustonMgr = regionalOffices[2][1]
```

The first index in brackets is for the outermost array (`regionalOffices`); the second index in brackets points to the item of the array returned by

```
regionalOffices[2].
```

Array Object Properties

constructor

See `string.constructor` (Chapter 34).

length

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

A true array object's `length` property reflects the number of entries in the array. An entry can be any kind of JavaScript value, including `null`. If an entry is in the 10th cell and the rest are `null`, the length of that array is 10. Note that because array index values are zero-based, the index of the last cell of an array is one less than the length. This characteristic makes it convenient to use the property as an automatic counter to append a new item to an array:

```
myArray[myArray.length] = valueOfAppendedItem
```

Thus, a generic function does not have to know which specific index value to apply to an additional item in the array.

prototype

Value: Variable or Function

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

Inside JavaScript, an array object has its dictionary definition of methods and `length` property—items that all array objects have in common. The `prototype` property enables your scripts to ascribe additional properties or methods that apply to all the arrays you create in the currently loaded documents. You can override this prototype, however, for any individual objects as you want.

To demonstrate how the prototype property works, Listing 37-5 creates a prototype property for all array objects generated from the static `Array` object. As the script generates new arrays (instances of the `Array` object, just as a `Date` object is an instance of the `Date` object), the property automatically becomes a part of those arrays. In one array, `c`, you override the value of the prototype `sponsor` property. By changing the value for that one object, you don't alter the value of the prototype for the `Array` object. Therefore, another array created afterward, `d`, still gets the original `sponsor` property value.

Listing 37-5: Adding a prototype Property

```
<HTML>
<HEAD>
<TITLE>Array prototypes</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
// add prototype to all Array objects
Array.prototype.sponsor = "DG"
a = new Array(5)
b = new Array(5)
c = new Array(5)
// override prototype property for one 'instance'
c.sponsor = "JS"
// this one picks up the original prototype
d = new Array(5)
</SCRIPT>
<BODY><H2>
<SCRIPT LANGUAGE="JavaScript">
document.write("Array a is brought to you by: " + a.sponsor + "<P>")
document.write("Array b is brought to you by: " + b.sponsor + "<P>")
document.write("Array c is brought to you by: " + c.sponsor + "<P>")
document.write("Array d is brought to you by: " + d.sponsor + "<P>")
</SCRIPT>
</H2>
</BODY>
</HTML>
```

You can assign properties and functions to a prototype. To assign a function, define the function as you normally would in JavaScript. Then assign the function to the prototype by name:

```
function newFunc(param1) {
    // statements
}
Array.prototype.newMethod = newFunc // omit parentheses in this reference
```

When you need to call upon that function (which has essentially become a new temporary method for the `Array` object), invoke it as you would any object method. Therefore, if an array named `CDCollection` has been created and a prototype method `showCoverImage()` has been attached to the array, the call to invoke the method for a tenth listing in the array is

```
CDCollection.showCoverImage(9)
```

where the parameter of the function uses the index value to perhaps retrieve an image whose URL is a property of an object assigned to the 10th item of the array.

Array Object Methods

After you have information stored in an array, JavaScript provides several methods to help you manage that data. These methods, all of which belong to array objects you create, have evolved over time, so observe carefully which browser versions a desired method works with.

`array.concat(array2)`

Returns: array Object.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The `array.concat()` method allows you to join two array objects into a new, third array object. The action of concatenating the arrays does not alter the contents or behavior of the two original arrays. To join the arrays, you refer to the first array object to the left of the period before the method; a reference to the second array is the parameter to the method. For example:

```
var array1 = new Array(1,2,3)
var array2 = new Array("a","b","c")
var array3 = array1.concat(array2)
// result: array with values 1,2,3,"a","b","c"
```

If an array element is a string or number value (not a string or number object), the values are copied from the original arrays into the new one. All connection with the original arrays ceases for those items. But if an original array element is a reference to an object of any kind, JavaScript copies a reference from the original array's entry into the new array. So if you make a change to either array's entry, the change occurs to the object, and both array entries reflect the change to the object.

Example (with Figure 37-1 and Listing 37-6) on the CD-ROM

Related Items: `array.join()` method.

array.join(separatorString)

Returns: String of entries from the array delimited by the *separatorString* value.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

You cannot view data in an array when it's in that form. Nor can you put an array into a form element for transmittal to a server CGI program. To make the transition from discrete array elements to string, the *array.join()* method handles what would otherwise be a nasty string manipulation exercise.

The sole parameter for this method is a string of one or more characters that you want to act as a delimiter between entries. For example, if you want commas between array items in their text version, the statement is

```
var arrayText = myArray.join(",")
```

Invoking this method does not change the original array in any way. Therefore, you need to assign the results of this method to another variable or a value property of a form element.

Example (with Listing 37-7) on the CD-ROM

Related Items: *string.split()* method.

array.pop()

array.push(valueOrObject)

array.shift()

array.unshift(valueOrObject)

Returns: One array entry value.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

The notion of a *stack* is well known to experienced programmers, especially those who know about the inner workings of assembly language at the CPU level. Even if you've never programmed a stack before, you have encountered the concept in real life many times. The classic analogy is the spring-loaded pile of cafeteria trays. If the pile were created one tray at a time, each tray would be pushed into the stack of trays. When a customer comes along, the topmost tray (the last one to be pushed onto the stack) gets popped off. The last one to be put on the stack is the first one to be taken off.

JavaScript in NN4+ and IE5.5 lets you turn an array into one of these spring-loaded stacks. But instead of placing trays on the pile, you can place any kind of data at either end of the stack, depending on which method you use to do the stacking. Similarly, you can extract an item from either end.

Perhaps the most familiar terminology for this is *push* and *pop*. When you `push()` a value onto an array, the value is appended as the last entry in the array. When you issue the `array.pop()` method, the last item in the array is removed from the stack and is returned, and the array shrinks in length by one. In the following sequence of statements, watch what happens to the value of the array used as a stack:

```
var source = new Array("Homer","Marge","Bart","Lisa","Maggie")
var stack = new Array()
    // stack = <empty>
stack.push(source[0])
    // stack = "Homer"
stack.push(source[2])
    // stack = "Homer","Bart"
var Simpson1 = stack.pop()
    // stack = "Homer" ; Simpson1 = "Bart"
var Simpson2 = stack.pop()
    // stack = <empty> ; Simpson2 = "Homer"
```

While `push()` and `pop()` work at the end of an array, another pair of methods works at the front. Their names are not as picturesque as `push()` and `pop()`. To insert a value at the front of an array, use the `array.unshift()` method; to grab the first element and remove it from the array, use `array.shift()`. Of course, you are not required to use these methods in matching pairs. If you `push()` a series of values onto the back end of an array, you can `shift()` them off from the front end without complaint. It all depends on how you need to process the data.

Related Items: `array.concat()`, `array.slice()` method.

`array.reverse()`

Returns: Array of entries in the opposite order of the original.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

Occasionally, you may find it more convenient to work with an array of data in reverse order. Although you can concoct repeat loops to count backward through index values, a CGI program on the server may prefer the data in a sequence opposite to the way it was most convenient for you to script it.

You can have JavaScript switch the contents of an array for you: Whatever element was last in the array becomes the 0 index item in the array. Bear in mind that if you do this, you're restructuring the original array, not copying it, even though the method also returns a copy of the reversed version. A reload of the document restores the order as written in the HTML document.

Example (with Listing 37-8) on the CD-ROM

Related Items: `array.sort()` method.

`array.slice(startIndex [, endIndex])`

Returns: Array.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Behaving as its like-named string method, `array.slice()` lets you extract a contiguous series of items from an array. The extracted segment becomes an entirely new array object. Values and objects from the original array have the same kind of behavior as arrays created with the `array.concat()` method.

One parameter is required — the starting index point for the extraction. If you don't specify a second parameter, the extraction goes all the way to the end of the array; otherwise the extraction goes to, *but does not include*, the index value supplied as the second parameter. For example, extracting Earth's neighbors from an array of planet names looks as the following.

```
var solarSys = new Array("Mercury","Venus","Earth","Mars","Jupiter","Saturn",
    "Uranus","Neptune","Pluto")
var nearby = solarSys.slice(1,4)
// result: new array of "Venus", "Earth", "Mars"
```

Related Items: `array.splice()`, `string.slice()` methods.

`array.sort([compareFunction])`

Returns: Array of entries in the order as determined by the `compareFunction` algorithm.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

JavaScript array sorting is both powerful and a bit complex to script if you haven't had experience with this kind of sorting methodology. The purpose, obviously, is to let your scripts sort entries of an array by almost any kind of criterion that you can associate with an entry. For entries consisting of strings, the criterion may be their alphabetical order or their length; for numeric entries, the criterion may be their numerical order.

Look first at the kind of sorting you can do with the `array.sort()` method by itself (for example, without calling a comparison function). When no parameter is specified, JavaScript takes a snapshot of the contents of the array and converts items to strings. From there, it performs a string sort of the values. ASCII values of characters govern the sort, which means that numbers are sorted by their string values, not their numeric values. This fact has strong implications if your array consists of numeric data: The value 201 sorts before 88, because the sorting mechanism compares the first characters of the strings (“2” versus “8”) to determine the sort order. For simple alphabetical sorting of string values in arrays, the plain `array.sort()` method does the trick.

Fortunately, additional intelligence is available that you can add to array sorting. The key tactic is to define a function that helps the `sort()` method compare items in the array. A comparison function is passed two values from the array (what you don’t see is that the `array.sort()` method rapidly sends numerous pairs of values from the array to help it sort through all entries). The comparison function lets the `sort()` method know which of the two items comes before the other, based on the value the function returns. Assuming that the function compares two values, `a` and `b`, the returned value reveals information to the `sort()` method, as shown in Table 37-1.

Table 37-1 Comparison Function Return Values

<i>Return Value Range</i>	<i>Meaning</i>
< 0	Value <code>b</code> should sort later than <code>a</code>
0	The order of <code>a</code> and <code>b</code> should not change
> 0	Value <code>a</code> should sort later than <code>b</code>

Consider the following example:

```
myArray = new Array(12, 5, 200, 80)
function compare(a,b) {
    return a - b
}
myArray.sort(compare)
```

The array has four numeric values in it. To sort the items in numerical order, you define a comparison function (arbitrarily named `compare()`), which is called from the `sort()` method. Note that unlike invoking other functions, the parameter of the `sort()` method uses a reference to the function, which lacks parentheses.

When the `compare()` function is called, JavaScript automatically sends two parameters to the function in rapid succession until each element has been compared with the others. Every time `compare()` is called, JavaScript assigns two of the array’s values to the parameter variables (`a` and `b`). In the preceding example, the returned value is the difference between `a` and `b`. If `a` is larger than `b`, then a positive value goes back to the `sort()` method, telling it to sort `a` later than `b` (that is, position `a` at a higher value index position than `b`). Therefore, `b` may end up at `myArray[0]`, whereas `a` ends up at a higher index-valued location. On the other

hand, if *a* is smaller than *b*, then the returned negative value tells `sort()` to put *a* in a lower index value spot than *b*.

Evaluations within the comparison function can go to great lengths, as long as some data connected with array values can be compared. For example, instead of numerical comparisons, as just shown, you can perform string comparisons. The following function sorts alphabetically by the last character of each array string entry:

```
function compare(a,b) {
    // last character of array strings
    var aComp = a.charAt(a.length - 1)
    var bComp = b.charAt(b.length - 1)
    if (aComp < bComp) {return -1}
    if (aComp > bComp) {return 1}
    return 0
}
```

First, this function extracts the final character from each of the two values passed to it. Then, because strings cannot be added or subtracted like numbers, you compare the ASCII values of the two characters, returning the corresponding values to the `sort()` method to let it know how to treat the two values being checked at that instant.

When an array's entries happen to be objects, you can even sort by properties of those objects. If you bear in mind that the *a* and *b* parameters of the sort function are references to two array entries, then by extension you can refer to properties of those objects. For example, if an array contains objects whose properties define information about employees, one of the properties of those objects can be the employee's age as a string. You can then sort the array based on the numeric equivalent of age property of the objects by way of the following comparison function:

```
function compare(a,b) {
    return parseInt(a.age) - parseInt(b.age)
}
```

Array sorting, unlike sorting routines you may find in other scripting languages, is not a stable sort. Not being stable means that succeeding sort routines on the same array are not cumulative. Also, remember that sorting changes the sort order of the original array. If you don't want the original array harmed, make a copy of it before sorting or reload the document to restore an array to its original order.

Should an array element be `null`, the method sorts such elements at the end of the sorted array starting with Navigator 4 (instead of leaving them in their original places as in Navigator 3).

Note

Unfortunately, this powerful method does not work in the Macintosh version of Navigator 3. Starting with Navigator 4, all platforms have the feature.

JavaScript array sorting is extremely powerful stuff. Array sorting is one reason why it's not uncommon to take the time during the loading of a page containing an IE XML data island to make a JavaScript copy of the data as an array of objects (see Chapter 57). Converting the XML to JavaScript arrays makes the job of sorting the data much easier and faster than cobbling together your own sorting routines on the XML elements.

Example (with Listing 37-9) on the CD-ROM

Related Items: `array.reverse()` method.

As I show you in Chapter 38, many regular expression object methods generate arrays as their result (for example, an array of matching values in a string). These special arrays have a custom set of named properties that assist your script in analyzing the findings of the method. Beyond that, these regular expression result arrays behave like all others.

```
array.splice(startIndex , deleteCount[ , item1[ , item2[ , ... itemN ] ] ] )
```

Returns: Array.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

If you need to remove items from the middle of an array, the `array.splice()` method (not implemented in IE5/Mac) simplifies a task that would otherwise require assembling a new array from selected items of the original array. The first of two required parameters is a zero-based index integer that points to the first item to be removed from the current array. The second parameter is another integer that indicates how many sequential items are to be removed from the array. Removing array items affects the length of the array, and those items that are removed are returned by the `splice()` method as their own array.

You can also use the `splice()` method to replace array items. Optional parameters beginning with the third let you provide data elements that are to be inserted into the array in place of the items being removed. Each added item can be any JavaScript data type, and the number of new items does not have to be equal to the number of items removed. In fact, by specifying a second parameter of zero, you can use `splice()` to insert one or more items into any position of the array.

Example on the CD-ROM

Related Items: `array.slice()` method.

`array.toLocaleString()`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

`array.toString()`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

The `array.toLocaleString()` and the older, more compatible `array.toString()` are methods to retrieve the contents of an array in string form. Browsers use the `toString()` method on their own whenever you attempt to display an array in text boxes, in which case the array items are comma-delimited.

The precise string conversion of the `toLocaleString()` is left up to the specific browser implementation. That IE5.5 and NN6 differ in some details is not surprising, even in the U.S. English versions of operating systems and browsers. For example, if the array contains integer values, IE5.5's `toLocaleString()` method returns the numbers comma-and-space-delimited, formatted with two digits to the right of the decimal (as if dollars and cents). NN6, on the other hand, returns just the integers, but these are also comma-and-space-delimited.

If you need to convert an array to a string for purposes of passing array data to other venues (for example, as data in a hidden text box submitted to a server or as search string data conveyed to another page), use the `array.join()` method instead. `Array.join()` gives you more reliable and flexible control over the item delimiters, and you are assured of the same results regardless of locale.

Related Items: `array.join()` method.

38

CHAPTER

The Regular Expression and RegExp Objects

Web programmers who have worked in Perl (and other Web application programming languages) know the power of regular expressions for processing incoming data and formatting data for readability in an HTML page or for accurate storage in a server database. Any task that requires extensive search and replacement of text can greatly benefit from the flexibility and conciseness of regular expressions. Navigator 4 and Internet Explorer 4 (more fully fleshed out in IE5.5) bring that power to JavaScript.

Most of the benefit of JavaScript regular expressions accrues to those who script their CGI programs on servers that support a JavaScript version that contains regular expressions. But that's not to exclude the client-side from application of this "language within a language." If your scripts perform client-side data validations or any other extensive text entry parsing, then consider using regular expressions, rather than cobbling together comparatively complex JavaScript functions to perform the same tasks.

Regular Expressions and Patterns

In several chapters earlier in this book, I describe expressions as any sequence of identifiers, keywords, and/or operators that evaluate to some value. A regular expression follows that description, but has much more power behind it. In essence, a regular expression uses a sequence of characters and symbols to define a pattern of text. Such a pattern is used to locate a chunk of text in a string by matching up the pattern against the characters in the string.

An experienced JavaScript writer may point out the availability of the `string.indexOf()` and `string.lastIndexOf()` methods that can instantly reveal whether a string contains a substring and even where in the string that substring begins. These methods work perfectly well when the match is exact,

In This Chapter

What regular expressions are

How to use regular expressions for text search-and-replace

How to apply regular expressions to string object methods

character for character. But if you want to do more sophisticated matching (for example, does the string contain a five-digit ZIP code?), you'd have to cast aside those handy string methods and write some parsing functions. That's the beauty of a regular expression: It lets you define a matching substring that has some intelligence about it and can follow guidelines you set as to what should or should not match.

The simplest kind of regular expression pattern is the same kind you use in the `string.indexOf()` method. Such a pattern is nothing more than the text that you want to match. In JavaScript, one way to create a regular expression is to surround the expression by forward slashes. For example, consider the string

```
Oh, hello, do you want to play Othello in the school play?
```

This string and others may be examined by a script whose job it is to turn formal terms into informal ones. Therefore, one of its tasks is to replace the word “hello” with “hi.” A typical brute force search-and-replace function starts with a simple pattern of the search string. In JavaScript, you define a pattern (a regular expression) by surrounding it with forward slashes. For convenience and readability, I usually assign the regular expression to a variable, as in the following example:

```
var myRegularExpression = /hello/
```

In concert with some regular expression or string object methods, this pattern matches the string “hello” wherever that series of letters appears. The problem is that this simple pattern causes problems during the loop that searches and replaces the strings in the example string: It finds not only the standalone word “hello,” but also the “hello” in “Othello.”

Trying to write another brute force routine for this search-and-replace operation that looks only for standalone words would be a nightmare. You can't merely extend the simple pattern to include spaces on either or both sides of “hello,” because there could be punctuation — a comma, a dash, a colon, or whatever — before or after the letters. Fortunately, regular expressions provide a shortcut way to specify general characteristics, including a feature known as a word boundary. The symbol for a word boundary is `\b` (backslash, lowercase b). If you redefine the pattern to include these specifications on both ends of the text to match, the regular expression creation statement looks like

```
var myRegularExpression = /\bhello\b/
```

When JavaScript uses this regular expression as a parameter in a special string object method that performs search-and-replace operations, it changes only the standalone word “hello” to “hi,” and passes over “Othello” entirely.

If you are still learning JavaScript and don't have experience with regular expressions in other languages, you have a price to pay for this power: Learning the regular expression lingo filled with so many symbols means that expressions sometimes look like cartoon substitutions for swear words. The goal of this chapter is to introduce you to regular expression syntax as implemented in JavaScript rather than engage in lengthy tutorials for this language. Of more importance in the long run is understanding how JavaScript treats regular expressions as objects and distinctions between instances of regular expression objects and the `RegExp` static object. I hope the examples in the following sections begin to reveal the powers of regular expressions. An in-depth treatment of the possibilities and idiosyncrasies of regular expressions can be found in *Mastering Regular Expressions* by Jeffrey E.F. Friedl (1997, O'Reilly & Associates, Inc.).

Language Basics

To cover the depth of the regular expression syntax, I divide the subject into three sections. The first covers simple expressions (some of which you've already seen). Then I get into the wide range of special characters used to define specifications for search strings. Last comes an introduction to the usage of parentheses in the language, and how they not only help in grouping expressions for influencing calculation precedence (as they do for regular math expressions), but also how they temporarily store intermediate results of more complex expressions for use in reconstructing strings after their dissection by the regular expression.

Simple patterns

A simple regular expression uses no special characters for defining the string to be used in a search. Therefore, if you wanted to replace every space in a string with an underscore character, the simple pattern to match the space character is

```
var re = / /
```

A space appears between the regular expression start-end forward slashes. The problem with this expression, however, is that it knows only how to find a single instance of a space in a long string. Regular expressions can be instructed to apply the matching string on a global basis by appending the `g` modifier:

```
var re = / /g
```

When this `re` value is supplied as a parameter to the `replace()` method that uses regular expressions (described later in this chapter), the replacement is performed throughout the entire string, rather than just once on the first match found. Notice that the modifier appears after the final forward slash of the regular expression creation statement.

Regular expression matching—like a lot of other aspects of JavaScript—is case-sensitive. But you can override this behavior by using one other modifier that lets you specify a case-insensitive match. Therefore, the following expression

```
var re = /web/i
```

finds a match for “web,” “Web,” or any combination of uppercase and lowercase letters in the word. You can combine the two modifiers together at the end of a regular expression. For example, the following expression is both case-insensitive and global in scope:

```
var re = /web/gi
```

In compliance with the ECMA-262 Edition 3 standard, IE5.5 and NN6 also allow a flag to force the regular expression to operate across multiple lines (meaning a carriage-return-delimited string) of a larger string. That modifier is the letter `m`.

Special characters

The regular expression in JavaScript borrows most of its vocabulary from the Perl regular expression. In a few instances, JavaScript offers alternatives to simplify the syntax, but also accepts the Perl version for those with experience in that arena.

Significant programming power comes from the way regular expressions allow you to include terse specifications about such facets as types of characters to accept in a match, how the characters are surrounded within a string, and how often a type of character can appear in the matching string. A series of escaped one-character commands (that is, letters preceded by the backslash) handle most of the character issues; punctuation and grouping symbols help define issues of frequency and range.

You saw an example earlier how `\b` specified a word boundary on one side of a search string. Table 38-1 lists the escaped character specifiers in JavaScript regular expressions. The vocabulary forms part of what are known as metacharacters — characters in expressions that are not matchable characters themselves, but act more as commands or guidelines of the regular expression language.

Table 38-1 JavaScript Regular Expression Matching Metacharacters

<i>Character</i>	<i>Matches</i>	<i>Example</i>
<code>\b</code>	Word boundary	<code>/\bor/</code> matches "origami" and "or" but not "normal" <code>/or\b/</code> matches "traitor" and "or" but not "perform" <code>/\bor\b/</code> matches full word "or" and nothing else
<code>\B</code>	Word non-boundary	<code>/\Bor/</code> matches "normal" but not "origami" <code>/or\B/</code> matches "normal" and "origami" but not "traitor" <code>/\Bor\B/</code> matches "normal" but not "origami" or "traitor"
<code>\d</code>	Numeral 0 through 9	<code>/\d\d\d/</code> matches "212" and "415" but not "B17"
<code>\D</code>	Non-numeral	<code>/\D\D\D/</code> matches "ABC" but not "212" or "B17"
<code>\s</code>	Single white space	<code>/over\sbite/</code> matches "over bite" but not "overbite" or "over bite"
<code>\S</code>	Single non-white space	<code>/over\Sbite/</code> matches "over-bite" but not "overbite" or "over bite"
<code>\w</code>	Letter, numeral, or underscore	<code>/A\w/</code> matches "A1" and "AA" but not "A+"
<code>\W</code>	Not letter, numeral, or underscore	<code>/A\W/</code> matches "A+" but not "A1" and "AA"
<code>.</code>	Any character except newline	<code>/.../</code> matches "ABC", "1+3", "A 3", or any three characters

Character	Matches	Example
[...]	Character set	/[AN]BC/ matches "ABC" and "NBC" but not "BBC"
[^...]	Negated character set	/[^AN]BC/ matches "BBC" and "CBC" but not "ABC" or "NBC"

Not to be confused with the metacharacters listed in Table 38-1 are the escaped string characters for tab (`\t`), newline (`\n`), carriage return (`\r`), formfeed (`\f`), and vertical tab (`\v`).

Let me further clarify about the [...] and [^...] metacharacters. You can specify either individual characters between the brackets (as shown in Table 38-1) or a contiguous range of characters or both. For example, the `\d` metacharacter can also be defined by `[0-9]`, meaning any numeral from zero through nine. If you only want to accept a value of 2 and a range from 6 through 8, the specification would be `[26-8]`. Similarly, the accommodating `\w` metacharacter is defined as `[A-Za-z0-9_]`, reminding you of the case-sensitivity of regular expression matches not otherwise modified.

All but the bracketed character set items listed in Table 38-1 apply to a single character in the regular expression. In most cases, however, you cannot predict how incoming data will be formatted—the length of a word or the number of digits in a number. A batch of extra metacharacters lets you set the frequency of the occurrence of either a specific character or a type of character (specified like the ones in Table 38-1). If you have experience in command-line operating systems, you can see some of the same ideas that apply to wildcards also apply to regular expressions. Table 38-2 lists the counting metacharacters in JavaScript regular expressions.

Table 38-2 JavaScript Regular Expression Counting Metacharacters

Character	Matches Last Character	Example
*	Zero or more times	/Ja*vaScript/ matches "JavaScript", "JavaScript", and "JaaavaScript" but not "JovaScript"
?	Zero or one time	/Ja?vaScript/ matches "JavaScript" or "JavaScript" but not "JaaavaScript"
+	One or more times	/Ja+vaScript/ matches "JavaScript" or "JaaavaScript" but not "JavaScript"
{n}	Exactly n times	/Ja{2}vaScript/ matches "JaaavaScript" but not "JavaScript" or "JavaScript"
{n,}	n or more times	/Ja{2,}vaScript/ matches "JaaavaScript" or "JaaavaScript" but not "JavaScript"
{n,m}	At least n, at most m times	/Ja{2,3}vaScript/ matches "JaaavaScript" or "JaaavaScript" but not "JavaScript"

Every metacharacter in Table 38-2 applies to the character immediately preceding it in the regular expression. Preceding characters may also be matching metacharacters from Table 38-1. For example, a match occurs for the following expression if the string contains two digits separated by one or more vowels:

```
/\d[aeiouy]+\d/
```

The last major contribution of metacharacters is helping the regular expression search a particular position in a string. By position, I don't mean something such as an offset—the matching functionality of regular expressions can tell me that. But, rather, whether the string to look for should be at the beginning or end of a line (if that is important) or whatever string is offered as the main string to search. Table 38-3 shows the positional metacharacters for JavaScript's regular expressions.

Table 38-3 JavaScript Regular Expression Positional Metacharacters

<i>Character</i>	<i>Matches Located</i>	<i>Example</i>
<code>^</code>	At beginning of a string or line	<code>/^Fred/</code> matches "Fred is OK" but not "I'm with Fred" or "Is Fred here?"
<code>\$</code>	At end of a string or line	<code>/Fred\$/</code> matches "I'm with Fred" but not "Fred is OK" or "Is Fred here?"

For example, you may want to make sure that a match for a roman numeral is found only when it is at the start of a line, rather than when it is used inline somewhere else. If the document contains roman numerals in an outline, you can match all the top-level items that are flush left with the document with a regular expression, such as the following:

```
/^[IVXMDCL]+\. /
```

This expression matches any combination of roman numeral characters followed by a period (the period is a special character in regular expressions, as shown in Table 38-1, so that you have to escape the period to offer it as a character), provided the roman numeral is at the beginning of a line and has no tabs or spaces before it. There would also not be a match in a line that contains, for example, the phrase "see Part IV" because the roman numeral is not at the beginning of a line.

Speaking of lines, a line of text is a contiguous string of characters delimited by a newline and/or carriage return (depending on the operating system platform). Word wrapping in TEXTAREA elements does not affect the starts and ends of true lines of text.

Grouping and backreferencing

Regular expressions obey most of the JavaScript operator precedence laws with regard to grouping by parentheses and the logical Or operator. One difference is that the regular expression Or operator is a single pipe character (`|`) rather than JavaScript's double pipe.

Parentheses have additional powers that go beyond influencing the precedence of calculation. Any set of parentheses (that is, a matched pair of left and right)

stores the results of a found match of the expression within those parentheses. Parentheses can be nested inside one another. Storage is accomplished automatically, with the data stored in an indexed array accessible to your scripts and to your regular expressions (although through different syntax). Access to these storage bins is known as *backreferencing*, because a regular expression can point backward to the result of an expression component earlier in the overall expression. These stored subcomponents come in handy for replace operations, as demonstrated later in this chapter.

Object Relationships

JavaScript has a lot going on behind the scenes when you create a regular expression and perform the simplest operation with it. As important as the regular expression language described earlier in this chapter is to applying regular expressions in your scripts, the JavaScript object interrelationships are perhaps even more important if you want to exploit regular expressions to the fullest.

The first concept to master is that two entities are involved: a regular expression instance object and the `RegExp` static object. Both objects are core objects of JavaScript and are not part of the document object model. Both objects work together, but have entirely different sets of properties that may be useful to your application.

When you create a regular expression (even via the `/.../` syntax), JavaScript invokes the new `RegExp()` constructor, much the way a new `Date()` constructor creates a date object around one specific date. The regular expression instance object returned by the constructor is endowed with several properties containing details of its data. At the same time, the single, static `RegExp` object maintains its own properties that monitor regular expression activity in the current window (or frame).

To help you see the typically unseen operations, I step you through the creation and application of a regular expression. In the process, I show you what happens to all of the related object properties when you use one of the regular expression methods to search for a match.

Note

Several properties of both the regular expression instance object and the static `RegExp` object shown in the following “walk-through” are not available in IE until version 5.5. All are available in NN4+. See the individual property listings later in this chapter for compatibility ratings.

The starting text that I use to search through is the beginning of Hamlet’s soliloquy (assigned to an arbitrary variable named `mainString`):

```
var mainString = "To be, or not to be: That is the question:"
```

If my ultimate goal is to locate each instance of the word “be,” I must first create a regular expression that matches the word “be.” I set the regular expression up to perform a global search when eventually called upon to replace itself (assigning the expression to an arbitrary variable named `re`):

```
var re = /\bbe\b/g
```

To guarantee that only complete words “be” are matched, I surround the letters with the word boundary metacharacters. The final “g” is the global modifier. The variable to which the expression is assigned, `re`, represents a regular expression object whose properties and values are as follows:

Object.PropertyName	Value
<code>re.source</code>	<code>"\bbe\b g"</code>
<code>re.global</code>	<code>true</code>
<code>re.ignoreCase</code>	<code>false</code>
<code>re.lastIndex</code>	<code>0</code>

A regular expression’s `source` property is the string consisting of the regular expression syntax (less the literal forward slashes). Each of the two possible modifiers, `g` and `i`, have their own properties, `global` and `ignoreCase`, whose values are Booleans indicating whether the modifiers are part of the source expression. The final property, `lastIndex`, indicates the index value within the main string at which the next search for a match should start. The default value for this property in a newly hatched regular expression is zero so that the search starts with the first character of the string. This property is read/write, so your scripts may want to adjust the value if they must have special control over the search process. As you see in a moment, JavaScript modifies this value over time if a global search is indicated for the object.

The `RegExp` constructor does more than just create regular expression objects. Like the `Math` object, the `RegExp` object is always “around” — one `RegExp` per window or frame — and tracks regular expression activity in a script. Its properties reveal what, if any, regular expression pattern matching has just taken place in the window. At this stage of the regular expression creation process, the `RegExp` object has only one of its properties set:

Object.PropertyName	Value
<code>RegExp.input</code>	
<code>RegExp.multiline</code>	<code>false</code>
<code>RegExp.lastMatch</code>	
<code>RegExp.lastParen</code>	
<code>RegExp.leftContext</code>	
<code>RegExp.rightContext</code>	
<code>RegExp.\$1</code>	
...	
<code>RegExp.\$9</code>	

The last group of properties (`$1` through `$9`) is for storage of backreferences. But because the regular expression I define above doesn’t have any parentheses in it,

these properties are empty for the duration of this examination and omitted from future listings in this “walk-through” section.

With the regular expression object ready to go, I invoke the `exec()` regular expression method, which looks through a string for a match defined by the regular expression. If the method is successful in finding a match, it returns a third object whose properties reveal a great deal about the item it found (I arbitrarily assign the variable `foundArray` to this returned object):

```
var foundArray = re.exec(mainString)
```

JavaScript includes a shortcut for the `exec()` method if you turn the regular expression object into a method:

```
var foundArray = re(mainString)
```

Normally, a script would check whether `foundArray` is `null` (meaning that there was no match) before proceeding to inspect the rest of the related objects. Because this is a controlled experiment, I know at least one match exists, so I first look into some other results. Running this simple method has not only generated the `foundArray` data, but also altered several properties of the `RegExp` and regular expression objects. The following shows you the current stage of the regular expression object:

<i>Object.PropertyName</i>	<i>Value</i>
<code>re.source</code>	<code>"\bbe\bg"</code>
<code>re.global</code>	<code>true</code>
<code>re.ignoreCase</code>	<code>false</code>
<code>re.lastIndex</code>	<code>5</code>

The only change is an important one: The `lastIndex` value has bumped up to 5. In other words, this one invocation of the `exec()` method must have found a match whose offset plus length of matching string shifts the starting point of any successive searches with this regular expression to character index 5. That’s exactly where the comma after the first “be” word is in the main string. If the global (g) modifier had not been appended to the regular expression, the `lastIndex` value would have remained at zero, because no subsequent search would be anticipated.

As the result of the `exec()` method, the `RegExp` object has had a number of its properties filled with results of the search:

<i>Object.PropertyName</i>	<i>Value</i>
<code>RegExp.input</code>	
<code>RegExp.multiline</code>	<code>false</code>
<code>RegExp.lastMatch</code>	<code>"be"</code>
<code>RegExp.lastParen</code>	
<code>RegExp.leftContext</code>	<code>"To "</code>
<code>RegExp.rightContext</code>	<code>", or not to be: That is the question:"</code>

From this object you can extract the string segment that was found to match the regular expression definition. The main string segments before and after the matching text are also available individually (in this example, the `leftContext` property has a space after “To”). Finally, looking into the array returned from the `exec()` method, some additional data is readily accessible:

<i>Object.PropertyName</i>	<i>Value</i>
<code>foundArray[0]</code>	<code>"be"</code>
<code>foundArray.index</code>	<code>3</code>
<code>foundArray.input</code>	<code>"To be, or not to be: That is the question:"</code>

The first element in the array, indexed as the zeroth element, is the string segment found to match the regular expression, which is the same as the `RegExp.lastMatch` value. The complete main string value is available as the `input` property. A potentially valuable piece of information to a script is the index for the start of the matched string found in the main string. From this last bit of data, you can extract from the found data array the same values as `RegExp.leftContext` (with `foundArray.input.substring(0, foundArray.index)`) and `RegExp.rightContext` (with `foundArray.input.substring(foundArray.index, foundArray[0].length)`).

Because the regular expression suggested a multiple execution sequence to fulfill the global flag, I can run the `exec()` method again without any change. While the JavaScript statement may not be any different, the search starts from the new `re.lastIndex` value. The effects of this second time through ripple through the resulting values of all three objects associated with this method:

```
var foundArray = re.exec(mainString)
```

Results of this execution are as follows (changes are in boldface).

<i>Object.PropertyName</i>	<i>Value</i>
<code>re.source</code>	<code>"\bbe\bg"</code>
<code>re.global</code>	<code>true</code>
<code>re.ignoreCase</code>	<code>false</code>
<code>re.lastIndex</code>	<code>19</code>
<code>RegExp.input</code>	
<code>RegExp.multiline</code>	<code>false</code>
<code>RegExp.lastMatch</code>	<code>"be"</code>
<code>RegExp.lastParen</code>	
<code>RegExp.leftContext</code>	<code>“, or not to ”</code>
<code>RegExp.rightContext</code>	<code>”: That is the question:"</code>

<i>Object.PropertyName</i>	<i>Value</i>
<code>foundArray[0]</code>	"be"
<code>foundArray.index</code>	17
<code>foundArray.input</code>	"To be, or not to be: That is the question:"

Because there was a second match, `foundArray` comes back again with data. Its `index` property now points to the location of the second instance of the string matching the regular expression definition. The regular expression object's `lastIndex` value points to where the next search would begin (after the second "be"). And the `RegExp` properties that store the left and right contexts have adjusted accordingly.

If the regular expression were looking for something less stringent than a hard-coded word, some other properties may also be different. For example, if the regular expression defined a format for a ZIP code, the `RegExp.lastMatch` and `foundArray[0]` values would contain the actual found ZIP codes, which would likely be different from one match to the next.

Running the same `exec()` method once more does not find a third match in my original `mainString` value, but the impact of that lack of a match is worth noting. First of all, the `foundArray` value is `null` — a signal to our script that no more matches are available. The regular expression object's `lastIndex` property reverts to zero, ready to start its search from the beginning of another string. Most importantly, however, the `RegExp` object's properties maintain the same values from the last successful match. Therefore, if you put the `exec()` method invocations in a repeat loop that exits after no more matches are found, the `RegExp` object still has the data from the last successful match, ready for further processing by your scripts.

Using Regular Expressions

Despite the seemingly complex hidden workings of regular expressions, JavaScript provides a series of methods that make common tasks involving regular expressions quite simple to use (assuming you figure out the regular expression syntax to create good specifications). In this section, I present examples of syntax for specific kinds of tasks for which regular expressions can be beneficial in your pages.

Is there a match?

I said earlier that you can use `string.indexOf()` or `string.lastIndexOf()` to look for the presence of simple substrings within larger strings. But if you need the matching power of regular expression, you have two other methods to choose from:

```
regexObject.test(string)
string.search(regexObject)
```

The first is a regular expression object method, the second a string object method. Both perform the same task and influence the same related objects, but

they return different values: a Boolean value for `test()` and a character offset value for `search()` (or `-1` if no match is found). Which method you choose depends on whether you need only a true/false verdict on a match or the location within the main string of the start of the substring.

Listing 38-1 demonstrates the `search()` method on a page that lets you get the Boolean and offset values for a match. Some default text and regular expression is provided (it looks for a five-digit number). You can experiment with other strings and regular expressions. Because this script creates a regular expression object with the new `RegExp()` constructor method, you do not include the literal forward slashes around the regular expression.

Getting information about a match

For the next application example, the task is not only to verify that a one-field date entry is in the desired format, but also to extract match components of the entry and use those values to perform further calculations in determining the day of the week. The regular expression in the example that follows is a fairly complex one, because it performs some rudimentary range checking to make sure the user doesn't enter a month over 12 or a date over 31. What it does not take into account is the variety of lengths of each month. But the regular expression and method invoked with it extract each date object component in such a way that you can perform additional validation on the range to make sure the user doesn't try to give September 31 days. Also be aware that this is not the only way to perform date validations in forms. Chapter 43 offers additional thoughts on the matter that work without regular expressions for backward compatibility.

Listing 38-2 contains a page that has a field for date entry, a button to process the date, and an output field for display of a long version of the date, including the day of the week. At the start of the function that does all the work, I create two arrays (using the JavaScript 1.2 literal array creation syntax) to hold the plain language names of the months and days. These arrays are used only if the user enters a valid date.

Next comes the regular expression to be matched against the user entry. If you can decipher all the symbols, you see that three components are separated by potential hyphen or forward slash entries (`[\\-\\/]`). These symbols must be escaped in the regular expression. Importantly, each of the three component definitions is surrounded by parentheses, which are essential for the various objects created with the regular expression to remember their values for extraction later.

Here is a brief rundown of what the regular expression is looking for:

- ♦ A string beginning after a word break
- ♦ A string value for the month that contains a 1 plus a 0 through 2; or an optional 0 plus a 1 through 9
- ♦ A hyphen or forward slash
- ♦ A string value for the date that starts with a 0 plus a 1 through 9; or starts with a 1 or 2 and ends with a 0 through 9; or starts with a 3 and ends with 0 or 1
- ♦ Another hyphen or forward slash
- ♦ A string value for the year that begins with 19 or 20, followed by two digits

An extra pair of parentheses must surround the `19|20` segment to make sure that either one of the matching values is attached to the two succeeding digits. Without the parentheses, the logic of the expression attaches the digits only to 20.

For invoking the regular expression action, I select the `exec()` method, assigning the returned object to the variable `matchArray`. I can also use the `string.match()` method here. Only if the match is successful (that is, all conditions of the regular expression specification are met) does the major processing continue in the script.

The parentheses around the segments of the regular expression instruct JavaScript to assign each found value to a slot in the `matchArray` object. The month segment is assigned to `matchArray[1]`, the date to `matchArray[2]`, and the year to `matchArray[3]` (`matchArray[0]` contains the entire matched string). Therefore, the script can extract each component to build a plain-language date string with the help of the arrays defined at the start of the function. I even use the values to create a new date object that calculates the day of the week for me. After I have all pieces, I concatenate them and assign the result to the value of the output field. If the regular expression `exec()` method doesn't match the typed entry with the expression, the script provides an error message in the field.

String replacement

To demonstrate using regular expressions for performing search-and-replace operations, I choose an application that may be of value to many page authors who have to display and format large numbers. Databases typically store large integers without commas. After five or six digits, however, such numbers are difficult for users to read. Conversely, if the user needs to enter a large number, commas help ensure accuracy.

Helping the procedure in JavaScript regular expressions is the `string.replace()` method (see Chapter 34). The method requires two parameters, a regular expression to search the string and a string to replace any match found in the string. The replacement string can be properties of the `RegExp` object as it stands after the most recent `exec()` method.

Listing 38-3 demonstrates how only a handful of script lines can do a lot of work when regular expressions handle the dirty work. The page contains three fields. Enter any number you want in the first one. A click of the Insert Commas button invokes the `commafy()` function in the page. The result is displayed in the second field. You can also enter a comma-filled number in the second field and click the Remove Commas button to see the inverse operation executed through the `decommafy()` function.

Specifications for the regular expression accept any positive or negative string of numbers. The keys to the action of this script are the parentheses around two segments of the regular expression. One set encompasses all characters not included in the second group: a required set of three digits. In other words, the regular expression is essentially working from the rear of the string, chomping off three-character segments and inserting a comma each time a set is found.

A `while` repeat loop cycles through the string and modifies the string (in truth, the string object is not being modified, but, rather, a new string is generated and assigned to the old variable name). I use the `test()` method because I don't need the returned value of the `exec()` method. The `test()` method impacts the regular expression and `RegExp` object properties the same way as the `exec()` method, but more efficiently. The first time the `test()` method runs, the part of the string that meets the first segment is assigned to the `RegExp.$1` property; the second segment, if any, is assigned to the `RegExp.$2` property. Notice that I'm not assigning the results of the `exec()` method to any variable, because for this application I don't need the array object generated by that method.

Next comes the tricky part. I invoke the `string.replace()` method, using the current value of the string (`num`) as the starting string. The pattern to search for is the regular expression defined at the head of the function. But the replacement string may look strange to you. The replacement string is replacing whatever the regular expression matches with the value of `RegExp.$1`, a comma, and the value of `RegExp.$2`. The `RegExp` object should not be part of the references used in the `replace()` method parameter. Because the regular expression matches the entire `num` string, the `replace()` method is essentially rebuilding the string from its components, plus adding a comma before the second component (the last free-standing three-digit section). Each `replace()` method invocation sets the value of `num` for the next time through the `while` loop and the `test()` method.

Looping continues until no matches occur—meaning that no more freestanding sets of three digits appear in the string. Then the results are written to the second field on the page.

Listing 38-3: Replacing Strings via Regular Expressions

</HTML>

```

Removing the commas is an even easier process. The regular expression is a comma with the global flag set. The `replace()` method reacts to the global flag by repeating the process until all matches are replaced. In this case, the replacement string is an empty string. For further examples of using regular expressions with string objects, see the discussions of the `string.match()`, `string.replace()`, and `string.split()` methods in Chapter 34.

Compatibility			✓	✓			✓	✓	✓

About this object

The regular expression object is created on the fly by your scripts. Each regular expression object contains its own pattern and other properties. Deciding which object creation style to use depends on the way the regular expression will be used in your scripts.

When you create a regular expression with the literal notation (that is, with the two forward slashes), the expression is automatically compiled for efficient processing as the assignment statement executes. The same is true when you use the new `RegExp()` constructor and specify a pattern (and optional modifier flags) as a parameter. Whenever the regular expression is fixed in the script, use the literal notation; when some or all of the regular expression is derived from an external source (for example, user input from a text field), assemble the expression as a parameter to the new `RegExp()` constructor. A compiled regular expression should be used at whatever stage the expression is ready to be applied and reused within the script. Compiled regular expressions are not saved to disk or given any more permanence beyond the life of a document's script (that is, it dies when the page unloads).

However, there may be times in which the specification for the regular expression changes with each iteration through a loop construction. For example, if statements in a `while` loop modify the content of a regular expression, compile the

expression inside the `while` loop, as shown in the following skeletal script fragment:

```
var srchText = form.search.value
var re = new RegExp() // empty constructor
while (someCondition) {
    re.compile("\\s+" + srchText + "\\s+", "gi")
    statements that change srchText
}
```

Each time through the loop, the regular expression object is both given a new expression (concatenated with metacharacters for one or more white spaces on both sides of some search text whose content changes constantly) and compiled into an efficient object for use with any associated methods.

Properties

constructor

See `string.constructor` (Chapter 34).

global ignoreCase

Value: Booleans

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

These two properties reflect the regular expression `g` and `i` modifier flags, if any, associated with a regular expression. Settings are read-only and are determined as the object is created. Each property is independent of the other.

Related Items: None.

lastIndex

Value: Integer

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

The `lastIndex` property indicates the index counter of the main string to be searched against the current regular expression object. When a regular expression object is created, this value is zero, meaning that there have been no searches with this object, and the default behavior of the first search is to start at the beginning of the string.

If the regular expression has the global modifier specified, the `lastIndex` property value advances to some higher value after the object is used in a method to match within a main string. The value is the position in the main string immediately after the previous matched string (and not including any character of the matched string). After locating the final match in a string, the method resets the `lastIndex` property to zero for the next time. You can also influence the behavior of matches by setting this value on the fly. For example, if you want the expression to begin its search at the fourth character of a target string, you change the setting immediately after creating the object, as follows:

```
var re = /somePattern/
re.lastIndex = 3 // fourth character in zero-based index system
```

Related Items: Match result object `index` property.

multiline

Value: Boolean

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `multiline` property reveals whether searches extend across multiple lines of a target string, as directed by the optional `m` modifier flag for a regular expression. NN4+ also includes the same-named property for the `RegExp` object (see the following section).

Related Items: `RegExp.multiline` property.

source

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The `source` property is simply the string representation of the regular expression used to define the object. This property is read-only.

Related Items: None.

Methods

`compile("pattern", ["g" | "i" | "m"])`

Returns: Regular expression object.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Use the `compile()` method to compile on the fly a regular expression whose content changes continually during the execution of a script. See the discussion earlier about this object for an example. Other regular expression creation statements (the literal notation and the new `RegExp()` constructor that passes a regular expression) automatically compile their expressions. The `m` pattern modifier is available in IE5.5+ and NN6+.

Related Items: None.

`exec("string")`

Returns: Match array object or `null`.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The `exec()` method examines the string passed as its parameter for at least one match of the specification defined for the regular expression object. The behavior of this method is similar to that of the `string.match()` method (although the `match()` method is more powerful in completing global matches). Typically, a call to the `exec()` method is made immediately after the creation of a regular expression object, as in the following example.

```
var re = /somePattern/
var matchArray = re.exec("someString")
```

Much happens as a result of the `exec()` method. Properties of both the regular expression object and window's `RegExp` object are updated based on the success of the match. The method also returns an object that conveys additional data about the operation. Table 38-4 shows the properties of this returned object.

Table 38-4 Match Found Array Object Properties

Property	Description
<code>index</code>	Zero-based index counter of the start of the match inside the string
<code>input</code>	Entire text of original string
<code>[0]</code>	String of most recent matched characters
<code>[1], ... [n]</code>	Parenthesized component matches

Some of the properties in this returned object echo properties in the `RegExp` object. The value of having them in the regular expression object is that their

contents are safely stowed in the object while the `RegExp` object and its properties may be modified soon by another call to a regular expression method. Items the two objects have in common are the `[0]` property (mapped to the `RegExp.lastMatch` property) and the `[1], . . . [n]` properties (the first nine of which map to `RegExp.$1, . . . RegExp.$9`). While the `RegExp` object stores only nine parenthesized subcomponents, the returned array object stores as many as are needed to accommodate parenthesis pairs in the regular expression.

If no match turns up between the regular expression specification and the string, the returned value is `null`. See Listing 38-2 for an example of how this method can be applied. An alternate shortcut syntax may be used for the `exec()` method. Turn the regular expression into a function, as in

```
var re = /somePattern/
var matchArray = re("someString")
```

Related Items: `string.match()` method.

`test("string")`

Returns: Boolean.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

The most efficient way to find out if a regular expression has a match in a string is to use the `test()` method. Returned values are `true` if a match exists and `false` if not. In case you need more information, a companion method, `string.search()`, returns the starting index value of the matching string. See Listing 38-1 for an example of this method in action.

Related Items: `string.search()` method.

Compatibility			✓	✓			✓	✓	✓

About this object

Beginning with Navigator 4 and Internet Explorer 4, the browser maintains a single instance of a `RegExp` object for each window or frame. The object oversees the action of all methods that involve regular expressions (including the few related string object methods). Properties of this object are exposed not only to JavaScript in the traditional manner, but also to a parameter of the method `string.replace()` for some shortcut access (see Listing 38-3).

With one `RegExp` object serving all regular expression-related methods in your document's scripts, you must exercise care in accessing or modifying this object's properties. You must make sure that the `RegExp` object has not been affected by another method. Most properties are subject to change as the result of any method involving a regular expression. This may be reason enough to use the properties of the array object returned by most regular expression methods instead of the `RegExp` properties. The former stick with a specific regular expression object even after other regular expression objects are used in the same script. The `RegExp` properties reflect the most recent activity, irrespective of the regular expression object involved.

In the following listings, I supply the long, JavaScript-like property names. But each property also has an abbreviated, Perl-like manner to refer to the same properties. You can use these shortcut property names in the `string.replace()` method if you need the values.

Properties

input

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

The `RegExp.input` property is the main string against which a regular expression is compared in search of a match. In all of the example listings earlier in this chapter, the property was `null`. Such is the case when the main string is supplied as a parameter to the regular expression-related method.

But many text-related document objects have an unseen relationship with the `RegExp` object. If a text, `TEXTAREA`, `SELECT`, or link object contains an event handler that invokes a function containing a regular expression, the `RegExp.input` property is set to the relevant textual data from the object. You don't have to specify any parameters for the event handler call or in the function called by the event handler. For text and `TEXTAREA` objects, the `input` property value becomes the content of the object; for the `SELECT` object, it is the text (not the value) of the selected option; and for a link, it is the text highlighted in the browser associated with the link (and reflected in the link's `text` property).

Having JavaScript set the `RegExp.input` property for you may simplify your script. You can invoke either of the regular expression methods without having to specify the main string parameter. When that parameter is empty, JavaScript applies the `RegExp.input` property to the task. You can also set this property on the fly if you want. The short version of this property is `$_` (dollar sign underscore).

Related Items: Matching array object `input` property.

multiline

Value: Boolean

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					

The `RegExp.multiline` property determines whether searches extend across multiple lines of a target string. This property is automatically set to `true` as an event handler of a `TEXTAREA` triggers a function containing a regular expression. You can also set this property on the fly if you want. The short version of this property is `$*`. This version of the property (as distinct from the `multiline` property of an instance of a regular expression) is not defined in the ECMA-262 specification and is supported only in NN4+.

Related Items: Regular expression instance object `multiline` property.

lastMatch

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

After execution of a regular expression-related method, any text in the main string that matches the regular expression specification is automatically assigned to the `RegExp.lastMatch` property. This value is also assigned to the `[0]` property of the object array returned after the `exec()` and `string.match()` methods find a match. The short version of this property is `$&`.

Related Items: Matching array object `[0]` property.

lastParen

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

When a regular expression contains many parenthesized subcomponents, the `RegExp` object maintains a list of the resulting strings in the `$1`, `...`, `$9` properties. You can also extract the value of the last matching parenthesized subcomponent with the `RegExp.lastParen` property, which is a read-only property. The short version of this property is `$+`.

Related Items: `RegExp.$1`, `...`, `$9` properties.

leftContext rightContext

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					✓

After a match is found in the course of one of the regular expression methods, the `RegExp` object is informed of some key contextual information about the match. The `leftContext` property contains the part of the main string to the left of (up to but not including) the matched string. Be aware that the `leftContext` starts its string from the point at which the most recent search began. Therefore, for second or subsequent times through the same string with the same regular expression, the `leftContext` substring varies widely from the first time through.

The `rightContext` consists of a string starting immediately after the current match and extending to the end of the main string. As subsequent method calls work on the same string and regular expression, this value obviously shrinks in length until no more matches are found. At this point, both properties revert to `null`. The short versions of these properties are `$`` and `$'` for `leftContext` and `rightContext`, respectively.

Related Items: None.

prototype

See `String.prototype` (Chapter 34).

\$1 . . . \$9

Value: String

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

As a regular expression method executes, any parenthesized result is stored in RegExp's nine properties reserved for just that purpose (called backreferences). The same values (and any beyond the nine that RegExp has space for) are stored in the array object returned with the `exec()` and `string.match()` methods. Values are stored in the order in which the left parenthesis of a pair appears in the regular expression, regardless of nesting of other components.

You can use these backreferences directly in the second parameter of the `string.replace()` method, without using the RegExp part of their address. The ideal situation is to encapsulate components that need to be rearranged or recombined with replacement characters. For example, the following script function turns a name that is last name first into first name last:

```
function swapEm() {
    var re = /(\w+),\s*(\w+)/
    var input = "Lincoln, Abraham"
    return input.replace(re,"$2 $1")
}
```

In the `replace()` method, the second parenthesized component (just the first name) is placed first, followed by a space and the first component. The original comma is discarded. You are free to combine these shortcut references as you like, including multiple times per replacement, if it makes sense to your application.

Control Structures and Exception Handling

You get up in the morning, go about your day's business, and then turn out the lights at night. That's not much different from what a program does from the time it starts to the time it ends. But along the way, both you and a program take lots of tiny steps, not all of which advance the "processing" in a straight line. At times, you have to control what's going on by making a decision or repeating tasks until the whole job is finished. Control structures are the facilities that make these tasks possible in JavaScript.

JavaScript control structures follow along the same lines of many programming languages, particularly with additions made in Navigator 4 and Internet Explorer 4. Basic decision-making and looping constructions satisfy the needs of just about all programming tasks.

Another vital program control mechanism — error (or exception) handling — is formally addressed in Edition 3 of the ECMA-262 language standard. The concept of exception handling is new to the JavaScript version that comes in IE5.5 and NN6, but it is well known to programmers in many other environments. Adopting exception handling techniques in your code can greatly enhance recovery from processing errors caused by errant user input or network glitches.

39

CHAPTER

In This Chapter

Branching script execution down multiple paths

Looping through ordered collections of data

Applying exception handling techniques

If and If. . .Else Decisions

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

JavaScript programs frequently have to make decisions based on the current values of variables or object properties. Such decisions can have only two possible outcomes at a time. The factor that determines the path that the program takes at these decision points is the truth of some statement. For example, when you enter a room of your home at night, the statement under test is something such as “It is too dark to see without a light.” If that statement is true, you switch on the light; if that statement is false, you carry on with your primary task.

Simple decisions

JavaScript syntax for this kind of simple decision always begins with the keyword `if`, followed by the condition to test, and then the statements that execute if the condition yields a true result. JavaScript uses no “then” keyword (as some other languages do); the keyword is implied by the way parentheses and braces surround the various components of this construction. The formal syntax is

```
if (condition) {
    statementsIfTrue
}
```

This construction means that if the condition is true, program execution takes a detour to execute statements inside the braces. No matter what happens, the program continues executing statements beyond the closing brace `}`. If household navigation were part of the scripting language, the code would look as this:

```
if (tooDark == true) {
    feel for light switch
    turn on light switch
}
```

If you’re not used to C/C++, the double equals sign may have caught your eye. You learn more about this type of operator in the next chapter, but for now, know that this operator compares the equality of items on either side of it. In other words, the condition statement of an `if` construction must always yield a Boolean (true or false) value. Some object properties, you may recall, are Booleans, so you can stick a reference to that property into the condition statement by itself. Otherwise, the condition statement consists of two values separated by a comparison operator, such as `==` (equals) or `!=` (does not equal).

Next, look at some real JavaScript. The following function receives a form object containing a text object called `entry`:

```
function notTooHigh(form) {
    if (parseInt(form.entry.value) > 100) {
        alert("Sorry, the value you entered is too high. Try again.")
    }
}
```

```

        return false
    }
    return true
}

```

The condition (in parentheses) tests the contents of the field against a hard-wired value of 100. If the entered value is larger than that, the function alerts you and returns a `false` value to the calling statement elsewhere in the script. But if the value is less than 100, all intervening code is skipped and the function returns `true`.

About (*condition*) expressions

A lot of condition testing for control structures compares a value against some very specific condition, such as a string's being empty or a value's being `null`. You can use a couple of shortcuts to take care of many circumstances. Table 39-1 details the values that evaluate to a `true` or `false` (or equivalent) to satisfy a control structure's *condition* expression.

Table 39-1 Condition Value Equivalents

<i>True</i>	<i>False</i>
Nonempty string	Empty string
Nonzero number	0
Nonnull value	Null
Object exists	Object doesn't exist
Property is defined	Undefined property

Instead of having to spell out an equivalency expression for a condition involving these kinds of values, you can simply supply the value to be tested. For example, if a variable named `myVal` may reach an `if` construction with a value of `null`, an empty string, or a string value for further processing, you can use the following shortcut:

```

if (myVal) {
    // do processing on myVal
}

```

All null or empty string conditions evaluate to `false`, so that only the cases of `myVal`'s being a processable value get inside the `if` construction. This mechanism is the same that you have seen elsewhere in this book to employ object detection for browser branching. For example, the code nested inside the following code segment executes only if the document object has an `images` array property:

```

if (document.images) {
    // do processing on image objects
}

```

What's with the Formatting?

Indentation of the `if` construction and the further indentation of the statements executed on a true condition are not required by JavaScript. What you see here, however, is a convention that most JavaScript scripters follow. As you write the code in your text editor, you can use the Tab key to make each indentation level. The browser ignores these tab characters when loading the HTML documents containing your scripts.

Complex decisions

The simple type of `if` construction described earlier is fine when the decision is to take a small detour before returning to the main path. But not all decisions — in programming or in life — are like that. To present two alternate paths in a JavaScript decision, you can add a component to the construction. The syntax is

```
if (condition) {  
    statementsIfTrue  
} else {  
    statementsIfFalse  
}
```

By appending the `else` keyword, you give the `if` construction a path to follow in case the condition evaluates to false. The *statementsIfTrue* and *statementsIfFalse* do not have to be balanced in any way: One statement can be one line of code, the other one hundred lines. But when either one of those branches completes, execution continues after the last closing brace. To demonstrate how this construction can come in handy, the following example is a script fragment that assigns the number of days in February based on whether or not the year is a leap year (using modulo arithmetic, explained in Chapter 40, to determine if the year is evenly divisible by four, and setting aside all other leap year calculation details for the moment):

```
var howMany = 0  
var theYear = 2002  
if (theYear % 4 == 0) {  
    howMany = 29  
} else {  
    howMany = 28  
}
```

Here is a case where execution has to follow only one of two possible paths to assign the number of days to the `howMany` variable. Had I not used the `else` portion, as in

```
var howMany = 0  
var theYear = 2002  
if (theYear % 4 == 0) {  
    howMany = 29  
}  
howMany = 28
```

then the variable would always be set to 28, occasionally after momentarily being set to 29. The `else` construction is essential in this case.

Nesting `if. . .else` statements

Designing a complex decision process requires painstaking attention to the logic of the decisions your script must process and the statements that must execute for any given set of conditions. The need for many complex constructions disappears with the advent of `switch` construction in NN4+ and IE4+ (described later in this chapter), but there may still be times when you must fashion complex decision behavior out of a series of nested `if. . .else` constructions. Without a JavaScript-aware text editor to help keep everything properly indented and properly terminated (with closing braces), you have to monitor the authoring process very carefully. Moreover, the error messages that JavaScript provides when a mistake occurs (see Chapter 45) may not point directly to the problem line but only to the region of difficulty.

Note

Another important point to remember about nesting `if. . .else` statements in JavaScript before Version 1.2 is that the language does not provide a mechanism for script execution to break out of a nested part of the construction. For that reason, you have to construct complex assemblies with extreme care to make sure only the desired statement executes for each set of conditions. Extensive testing, of course, is also required (see Chapter 45).

To demonstrate a deeply nested set of `if. . .else` constructions, Listing 39-1 presents a simple user interface to a complex problem. A single text object asks the user to enter one of three letters — A, B, or C. The script behind that field processes a different message for each of the following conditions:

- ♦ The user enters no value.
- ♦ The user enters A.
- ♦ The user enters B.
- ♦ The user enters C.
- ♦ The user enters something entirely different.

Listing 39-1: Deeply Nested `if. . .else` Constructions

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function testLetter(form){
    inpVal = form.entry.value // assign to shorter variable name
    if (inpVal != "") { // if entry is not empty then dive in...
        if (inpVal == "A") { // Is it an "A"?
            alert("Thanks for the A.")
        } else if (inpVal == "B") { // No. Is it a "B"?
```

Continued

Listing 39-1 (continued)

```

        alert("Thanks for the B.")
    } else if (inpVal == "C") { // No. Is it a "C"?
        alert("Thanks for the C.")
    } else { // Nope. None of the above
        alert("Sorry, wrong letter or case.")
    }
} else { // value was empty, so skipped all other stuff above
    alert("You did not enter anything.")
}
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
Please enter A, B, or C:
<INPUT TYPE="text" NAME="entry" onChange="testLetter(this.form)">
</FORM>
</BODY>
</HTML>

```

Each condition executes only the statements that apply to that particular condition, even if it takes several queries to find out what the entry is. You do not need to break out of the nested construction because when a true response is found, the relevant statement executes, and no other statements occur in the execution path to run.

Even if you understand how to construct a hair-raising nested construction, such as the one in Listing 39-1, the trickiest part is making sure that each left brace has a corresponding right brace. My technique for ensuring this pairing is to enter the right brace immediately after I type the left brace. I typically type the left brace, press Enter twice (once to open a free line for the next statement, once for the line that is to receive the right brace); tab, if necessary, to the same indentation as the line containing the left brace; and then type the right brace. Later, if I have to insert something indented, I just push down the right braces that I entered earlier. If I keep up this methodology throughout the process, the right braces appear at the desired indentation after I'm finished, even if the braces end up being dozens of lines below their original spot.

Conditional Expressions

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

While I'm showing you decision-making constructions in JavaScript, now is a good time to introduce a special type of expression that you can use in place of an

`if. . .else` control structure for a common type of decision — the instance where you want to assign one of two values to a variable, depending on the outcome of some condition. The formal definition for the conditional expression is as follows:

```
variable = (condition) ? val1 : val2
```

This expression means that if the Boolean result of the `condition` statement is true, JavaScript assigns `val1` to the variable; otherwise, it assigns `val2` to the variable. Like other instances of condition expressions, this one must also be written inside parentheses. The question mark is key here, as is the colon separating the two possible values.

A conditional expression, though not particularly intuitive or easy to read inside code, is very compact. Compare an `if. . .else` version of an assignment decision that follows

```
var collectorStatus
if (CDCount > 500) {
    collectorStatus = "fanatic"
} else {
    collectorStatus = "normal"
}
```

with the conditional expression version:

```
var collectorStatus = (CDCount > 500) ? "fanatic" : "normal"
```

The latter saves a lot of code lines (although the internal processing is the same as that of an `if. . .else` construction). Of course, if your decision path contains more statements than just one setting the value of a variable, the `if. . .else` or `switch` construction is preferable. This shortcut, however, is a handy one to remember if you need to perform very binary actions, such as setting a true-or-false flag in a script.

Repeat (for) Loops

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

As you have seen in numerous examples throughout other chapters, the capability to cycle through every entry in an array or through every item of a form element is vital to many JavaScript scripts. Perhaps the most typical operation is inspecting a property of many similar items in search of a specific value, such as to determine which radio button in a group is selected. One JavaScript structure that allows for these repetitious excursions is the `for` loop, so named after the keyword that begins the structure. Two other structures, called the `while` loop and `do-while` loop, are covered in following sections.

The JavaScript `for` loop lets a script repeat a series of statements any number of times and includes an optional loop counter that can be used in the execution of the statements. The following is the formal syntax definition:

```
for ( [initial expression]; [condition]; [update expression] ) {
    statements
}
```

The three statements inside the parentheses (parameters to the `for` statement) play a key role in the way a `for` loop executes.

An initial expression in a `for` loop is executed one time, the first time the `for` loop begins to run. The most common application of the initial expression is to assign a name and starting value to a loop counter variable. Thus, seeing a `var` statement that both declares a variable name and assigns an initial value (generally 0 or 1) to it is not uncommon. An example is

```
var i = 0
```

You can use any variable name, but conventional usage calls for the letter `i`, which is short for *index*. If you prefer the word `counter` or another word that reminds you of what the variable represents, that's fine, too. In any case, the important point to remember about this statement is that it executes once at the outset of the `for` loop.

The second statement is a *condition*, precisely like the `condition` statement you saw in `if` constructions earlier in this chapter. When a loop-counting variable is established in the initial expression, the `condition` statement usually defines how high the loop counter should go before the looping stops. Therefore, the most common statement here is one that compares the loop counter variable against some fixed value—is the loop counter less than the maximum allowed value? If the condition is false at the start, the body of the loop is not executed. But if the loop does execute, then every time execution comes back around to the top of the loop, JavaScript reevaluates the condition to determine the current result of the expression. If the loop counter increases with each loop, eventually the counter value goes beyond the value in the `condition` statement, causing the `condition` statement to yield a Boolean value of `false`. The instant that happens, execution drops out of the `for` loop entirely.

The final statement, the *update expression*, is executed at the end of each loop execution—after all statements nested inside the `for` construction have run. Again, the loop counter variable can be a factor here. If you want the counter value to increase by one the next time through the loop (called incrementing the value), you can use the JavaScript operator that makes that happen: the `++` operator appended to the variable name. That task is the reason for the appearance of all those `i++` symbols in the `for` loops that you've seen already in this book. You're not limited to incrementing by one. You can increment by any multiplier you want or even drive a loop counter backward by decrementing the value (`i--`).

Now, take this knowledge and beef up the formal syntax definition with one that takes into account a typical loop-counting variable, `i`, and the common ways to use it:

```
// incrementing loop counter
for (var i = minValue; i <= maxValue; i++) {
    statements
}
```

```

}
// decrementing loop counter
for (var i = maxValue; i >= minValue; i--) {
    statements
}

```

In the top format, the variable, `i`, is initialized at the outset to a value equal to that of `minValue`. Variable `i` is immediately compared against `maxValue`. If `i` is less than or equal to `maxValue`, processing continues into the body of the loop. At the end of the loop, the update expression executes. In the top example, the value of `i` is incremented by 1. Therefore, if `i` is initialized as 0, then the first time through the loop, the `i` variable maintains that 0 value during the first execution of statements in the loop. The next time around, the variable has the value of 1.

As you may have noticed in the formal syntax definition, each of the parameters to the `for` statement is optional. For example, the statements that execute inside the loop may control the value of the loop counter based on data that gets manipulated in the process. Therefore, the update statement would probably interfere with the intended running of the loop. But I suggest that you use all three parameters until such time as you feel absolutely comfortable with their roles in the `for` loop. If you omit the condition statement, for instance, and you don't program a way for the loop to exit on its own, your script may end up in an infinite loop—which does your users no good.

Putting the loop counter to work

Despite its diminutive appearance, the `i` loop counter (or whatever name you want to give it) can be a powerful tool for working with data inside a repeat loop. For example, examine a version of the classic JavaScript function that creates a Navigator 2-compatible array while initializing entries to a value of 0:

```

// initialize array with n entries
function MakeArray(n) {
    this.length = n
    for (var i = 1; i <= n; i++) {
        this[i] = 0
    }
    return this
}

```

The loop counter, `i`, is initialized to a value of 1, because you want to create an array of empty entries (with value 0) starting with the one whose index value is 1 (the zeroth entry is assigned to the `length` property) in the previous line. In the condition statement, the loop continues to execute as long as the value of the counter is less than or equal to the number of entries being created (`n`). After each loop, the counter increments by 1. In the nested statement that executes within the loop, you use the value of the `i` variable to substitute for the index value of the assignment statement:

```
this[i] = 0
```

The first time the loop executes, the value expression evaluates to

```
this[1] = 0
```

The next time, the expression evaluates to

```
this[2] = 0
```

and so on, until all entries are created and stuffed with 0.

Recall the HTML page in Listing 37-3, where a user chooses a regional office from a SELECT list (triggering a script to look up the manager's name and sales quota for that region). Because the regional office names are stored in an array, the page could be altered so that a script populates the SELECT element's options from the array. That way, if there is ever a change to the alignment of regional offices, there need be only one change to the array of offices, and the HTML doesn't have to be modified. As a reminder, here is the definition of the regional offices array, created while the page loads:

```
var regionalOffices = new Array("New York", "Chicago", "Houston", "Portland")
```

A script inside the HTML form can be used to dynamically generate the SELECT list as follows:

```
<SCRIPT LANGUAGE="JavaScript">
var elem = "" // start assembling next part of page and form
elem += "<P>Select a regional office: "
elem += "<SELECT NAME='offices' onChange='getData(this.form)'"
// build options list from array office names
for (var i = 0; i < regionalOffices.length; i++) {
    elem += "<OPTION" // OPTION tags
    if (i == 0) { // pre-select first item in list
        elem += " SELECTED"
    }
    elem += ">" + regionalOffices[i]
}
elem += "</SELECT></P>" // close SELECT item tag
document.write(elem) // write element to the page
</SCRIPT>
```

Notice one important point about the condition statement of the for loop: JavaScript extracts the length property from the array to be used as the loop counter boundary. From a code maintenance and stylistic point of view, this method is preferable to hard-wiring a value there. If the company added a new regional office, you would make the addition to the array “database,” whereas everything else in the code would adjust automatically to those changes, including creating a longer pop-up menu in this case.

Notice, too, that the operator for the condition statement is less-than (<): The zero-based index values of arrays mean that the maximum index value we can use is one less than the actual count of items in the array. This is vital information, because the index counter variable (i) is used as the index to the regionalOffices array each time through the loop to read the string for each item's entry. You also use the counter to determine which is the first option, so that you can take a short detour (via the if construction) to add the SELECTED attribute to the first option's definition.

The utility of the loop counter in for loops often influences the way you design data structures, such as two-dimensional arrays (see Chapter 37) for use as databases. Always keep the loop-counter mechanism in the back of your mind when

you begin writing JavaScript script that relies on collections of data that you embed in your documents.

Breaking out of a loop

Some loop constructions perform their job as soon as a certain condition is met, at which point they have no further need to continue looping through the rest of the values in the loop counter's range. A common scenario for this is the cycling of a loop through an entire array in search of a single entry that matches some criterion. That criterion test is set up as an `if` construction inside the loop. If that criterion is met, you break out of the loop and let the script continue with the more meaningful processing of succeeding statements in the main flow. To accomplish that exit from the loop, use the `break` statement. The following schematic shows how the `break` statement may appear in a `for` loop:

```
for (var i = 0; i < array.length; i++) {
    if (array[i].property == magicValue) {
        statements that act on entry array[i]
        break
    }
}
```

The `break` statement tells JavaScript to bail out of the nearest `for` loop (in case you have nested `for` loops). Script execution then picks up immediately after the closing brace of the `for` statement. The variable value of `i` remains whatever it was at the time of the `break`, so that you can use that variable later in the same script to access, say, that same array entry.

I use a construction similar to this in Chapter 24. There, the discussion of radio buttons demonstrates this construction, where, in Listing 24-8, you see a set of radio buttons whose `VALUE` attributes contain the full names of four members of the Three Stooges. A function uses a `for` loop to find out which button was selected and then uses that item's index value—after the `for` loop breaks out of the loop—to alert the user. Listing 39-2 (not on the CD-ROM) shows the relevant function.

Listing 39-2: Breaking Out of a for Loop

```
function fullName(form) {
    for (var i = 0; i < form.stooges.length; i++) {
        if (form.stooges[i].checked) {
            break
        }
    }
    alert("You chose " + form.stooges[i].value + ".")
}
```

In this case, breaking out of the `for` loop was for more than mere efficiency; the value of the loop counter (frozen at the break point) is used to summon a different property outside of the `for` loop. In NN4+ and IE4+, the `break` statement assumes additional powers in cooperation with the new `label` feature of control structures. This subject is covered later in this chapter.

Directing loop traffic with `continue`

One other possibility in a `for` loop is that you may want to skip execution of the nested statements for just one condition. In other words, as the loop goes merrily on its way round and round, executing statements for each value of the loop counter, one value of that loop counter may exist for which you don't want those statements to execute. To accomplish this task, the nested statements need to include an `if` construction to test for the presence of the value to skip. When that value is reached, the `continue` command tells JavaScript to immediately skip the rest of the body, execute the `update` statement, and loop back around to the top of the loop (also skipping the `condition` statement part of the `for` loop's parameters).

To illustrate this construction, you create an artificial example that skips over execution when the counter variable is the superstitious person's unlucky 13:

```
for (var i = 0; i <= 20; i++) {
  if (i == 13) {
    continue
  }
  statements
}
```

In this example, the `statements` part of the loop executes for all values of `i` except 13. The `continue` statement forces execution to jump to the `i++` part of the loop structure, incrementing the value of `i` for the next time through the loop. In the case of nested `for` loops, a `continue` statement affects the `for` loop in whose immediate scope the `if` construction falls. The `continue` statement is enhanced in NN4+ and IE4+ in cooperation with the new `label` feature of control structures. This subject is covered later in this chapter.

The while Loop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

The `for` loop is not the only kind of repeat loop you can construct in JavaScript. Another statement, called a `while` statement, sets up a loop in a slightly different format. Rather than providing a mechanism for modifying a loop counter, a `while` repeat loop assumes that your script statements will reach a condition that forcibly exits the repeat loop.

The basic syntax for a `while` loop is

```
while (condition) {
  statements
}
```

The `condition` expression is the same kind that you saw in `if` constructions and in the middle parameter of the `for` loop. You introduce this kind of loop if some condition exists in your code (evaluates to `true`) before reaching this loop. The loop then performs some action, which affects that condition repeatedly until that

condition becomes `false`. At that point, the loop exits, and script execution continues with statements after the closing brace. If the statements inside the `while` loop do not affect the values being tested in *condition*, your script never exits, and it becomes stuck in an infinite loop.

Many loops can be rendered with either the `for` or `while` loops. In fact, Listing 39-3 (not on the CD-ROM) shows a `while` loop version of the `for` loop from Listing 39-2.

Listing 39-3: A while Loop Version of Listing 39-2

```
function fullName(form) {
    var i = 0
    while (!form.stooges[i].checked) {
        i++
    }
    alert("You chose " + form.stooges[i].value + ".")
}
```

One point you may notice is that if the condition of a `while` loop depends on the value of a loop counter, the scripter is responsible for initializing the counter prior to the `while` loop construction and managing its value within the `while` loop.

Should you need their powers, the `break` and `continue` control statements work inside `while` loops as they do in `for` loops. But because the two loop styles treat their loop counters and conditions differently, be extra careful (do lots of testing) when applying `break` and `continue` statements to both kinds of loops.

No hard-and-fast rules exist for which type of loop construction to use in a script. I generally use `while` loops only when the data or object I want to loop through is already a part of my script before the loop. In other words, by virtue of previous statements in the script, the values for any condition or loop counting (if needed) are already initialized. But if I need to cycle through an object's properties or an array's entries to extract some piece of data for use later in the script, I favor the `for` loop.

Another point of style, particularly with the `for` loop, is where a scripter should declare the `i` variable. Some programmers prefer to declare (or initialize if initial values are known) all variables in the opening statements of a script or function. That is why you tend to see a lot of `var` statements in those positions in scripts. If you have only one `for` loop in a function, for example, nothing is wrong with declaring and initializing the `i` loop counter in the initial expression part of the `for` loop (as demonstrated frequently in the previous sections). But if your function utilizes multiple `for` loops that reuse the `i` counter variable (that is, the loops run completely independently of one another), then you can declare the `i` variable once at the start of the function and simply assign a new initial value to `i` in each `for` construction.

The do-while Loop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

JavaScript in NN4+ and IE4+ brings you one more looping construction, called the `do-while` loop. The formal syntax for this construction is as follows:

```
do {
    statements
} while (condition)
```

An important difference distinguishes the `do-while` loop from the `while` loop. In the `do-while` loop, the statements in the construction always execute at least one time before the condition can be tested; in a `while` loop, the statements may never execute if the condition tested at the outset evaluates to `false`.

Use a `do-while` loop when you know for certain that the looped statements are free to run at least one time. If the condition may not be met the first time, use the `while` loop. For many instances, the two constructions are interchangeable, although only the `while` loop is compatible with all scriptable browsers.

Looping through Properties (for-in)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

JavaScript includes a variation of the `for` loop, called a `for-in` loop, which has special powers of extracting the names and values of any object property currently in the browser's memory. The syntax looks like this:

```
for (var in object) {
    statements
}
```

The `object` parameter is not the string name of an object but a reference to the object itself. JavaScript delivers an object reference if you provide the name of the object as an unquoted string, such as `window` or `document`. Using the `var` variable, you can create a script that extracts and displays the range of properties for any given object.

Listing 39-4 shows a page containing a utility function that you can insert into your HTML documents during the authoring and debugging stages of designing a JavaScript-enhanced page. In the example, the current `window` object is examined and its properties are presented in the page.

Listing 39-4: Property Inspector Function

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function showProps(obj,objName) {
    var result = ""
```

```

    for (var i in obj) {
        result += objName + "." + i + " = " + obj[i] + "<BR>"
    }
    return result
}
</SCRIPT>
</HEAD>
<BODY>
<B>Here are the properties of the current window:</B><P>
<SCRIPT LANGUAGE="JavaScript">
document.write(showProps(window, "window"))
</SCRIPT>
</BODY>
</HTML>

```

For debugging purposes, you can revise the function slightly to display the results in an alert dialog box. Replace the `
` HTML tag with the `\n` carriage return character for a nicely formatted display in the alert dialog box. You can call this function from anywhere in your script, passing both the object reference and a string to it to help you identify the object after the results appear in an alert dialog box. If the `showProps()` function looks familiar to you, it is because it closely resembles the property inspector routines of The Evaluator (see Chapter 13). In Chapter 45, you can see how to embed functionality of The Evaluator into a page under construction so that you can view property values while debugging your scripts.

The with Statement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

A `with` statement enables you to preface any number of statements by advising JavaScript on precisely which object your scripts will be talking about, so that you don't have to use full, formal addresses to access properties or invoke methods of the same object. The formal syntax definition of the `with` statement is as follows:

```

with (object) {
    statements
}

```

The object reference is a reference to any valid object currently in the browser's memory. An example of this appears in Chapter 35's discussion of the `Math` object. By embracing several `Math`-encrusted statements inside a `with` construction, your scripts can call the properties and methods without having to make the object part of every reference to those properties and methods.

An advantage of the `with` structure is that it can make heavily object-dependent statements easier to read and understand. Consider this long version of a function that requires multiple calls to the same object (but different properties):

```
function seeColor(form) {
    newColor = (form.colorsList.options[form.colorsList.selectedIndex].text)
    return newColor
}
```

Using the `with` structure, you can shorten the long statement:

```
function seeColor(form) {
    with (form.colorsList) {
        newColor = (options[selectedIndex].text)
    }
    return newColor
}
```

When JavaScript encounters an otherwise unknown identifier inside a `with` statement, it tries to build a reference out of the object specified as its parameter and that unknown identifier. You cannot, however, nest `with` statements that build on one another. For instance, in the preceding example, you cannot have a `with (colorsList)` nested inside a `with (form)` statement and expect JavaScript to create a reference to `options` out of the two object names.

As clever as the `with` statement may seem, be aware that it introduces some inherent performance penalties in your script (because of the way the JavaScript interpreter must artificially generate references). You probably won't notice degradation with occasional use of this construction, but if it's used inside a loop that must iterate many times, processing speed will almost certainly be affected negatively.

Labeled Statements

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Crafting multiple nested loops can sometimes be difficult when the final condition your script is looking for is met deep inside the nests. The problem is that the `break` or `continue` statement by itself has scope only to the nearest loop level. Therefore, even if you break out of the inner loop, the outer loop(s) continue to execute. If all you want to do is exit the function after the condition is met, a simple `return` statement performs the same job as some other languages' exit command. But if you also need some further processing within that function after the condition is met, you need the NN4+ and IE4+ facility that lets you assign labels to blocks of JavaScript statements. Your `break` and `continue` statements can then alter their scope to apply to a labeled block other than the one containing the statement.

A *label* is any identifier (that is, name starting with a letter and containing no spaces or odd punctuation other than an underscore) followed by a colon

preceding a logical block of executing statements, such as an `if . . . then` or loop construction. The formal syntax looks like the following:

```
labelID:
    statements
```

For a `break` or `continue` statement to apply itself to a labeled group, the label is added as a kind of parameter to each statement, as in

```
break labelID
continue labelID
```

To demonstrate how valuable this can be in the right situation, Listing 39-5 contains two versions of the same nested loop construction. The goal of each version is to loop through two different index variables until both values equal the target values set outside the loop. When those targets are met, the entire nested loop construction should break off and continue processing afterward. To help you visualize the processing that goes on during the execution of the loops, the scripts output intermediate and final results to a textarea.

In the version without labels, when the targets are met, only the simple `break` statement is issued. This breaks the inner loop at that point, but the outer loop picks up on the next iteration. By the time the entire construction has ended, a lot of wasted processing has gone on. Moreover, the values of the counting variables max themselves out, because the loops execute in their entirety several times after the targets are met.

But in the labeled version, the inner loop breaks out of the labeled outer loop as soon as the targets are met. Far fewer lines of code are executed, and the loop counting variables are equal to the targets, as desired. Experiment with Listing 39-5 by changing the `break` statements to `continue` statements. Then closely analyze the two results in the Results textarea to see how the two versions behave.

Listing 39-5: Labeled Statements

```
<HTML>
<HEAD>
<TITLE>Breaking Out of Nested Labeled Loops</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var targetA = 2
var targetB = 2
var range = 5
function run1() {
    var out = document.forms[0].output
    out.value = "Running WITHOUT labeled break\n"
    for (var i = 0; i <= range; i++) {
        out.value += "Outer loop #" + i + "\n"
        for (var j = 0; j <= range; j++) {
            out.value += "  Inner loop #" + j + "\n"
            if (i == targetA && j == targetB) {
                out.value += "**BREAKING OUT OF INNER LOOP**\n"
                break
            }
        }
    }
}
```

Continued

The switch Statement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

In some circumstances, a binary—true or false—decision path is not enough to handle the processing in your script. An object property or variable value may contain any one of several values, and a separate execution path is required for

each one. In the past, the way to accommodate this was with a series of `if . . . else` constructions. The more conditions you must test, the less efficient the processing is, because each condition must be tested. Moreover, the sequence of clauses and braces can get very confusing.

In NN4+ and IE4+, a control structure in use by many languages comes to JavaScript. The implementation is similar to that of Java and C, using the `switch` and `case` keywords. The basic premise is that you can create any number of execution paths based on the value of some expression. At the beginning of the structure, you identify what that expression is and then, for each execution path, assign a label matching a particular value.

The formal syntax for the `switch` statement is

```
switch (expression) {
  case label1:
    statements
    [break]
  case label2:
    statements
    [break]
  ...
  [default:
    statements]
}
```

The *expression* parameter of the `switch` statement can evaluate to any string or number value. Labels are not surrounded by quotes, even if the labels represent string values of the expression. Notice that the `break` statements are optional. A `break` statement forces the `switch` expression to bypass all other checks of succeeding labels against the expression value. Another option is the `default` statement, which provides a catchall execution path when the expression value does not match any of the `case` statement labels. If you'd rather not have any execution take place with a non-matching expression value, omit the `default` part of the construction.

To demonstrate the syntax of a working `switch` statement, Listing 39-6 provides the skeleton of a larger application of this control structure. The page contains two separate arrays of different product categories. Each product has its name and price stored in its respective array. A `SELECT` list displays the product names. After a user chooses a product, the script looks up the product name in the appropriate array and displays the price.

The trick behind this application is the values assigned to each product in the `select` list. While the displayed text is the product name, the `VALUE` attribute of each `<OPTION>` tag is the array category for the product. That value is the expression used to decide which branch to follow. Notice, too, that I assign a label to the entire `switch` construction. The purpose of that is to let the deeply nested repeat loops for each case completely bail out of the `switch` construction (via a labeled `break` statement) whenever a match is made. You can extend this example to any number of product category arrays with additional `case` statements to match.

Listing 39-6: The switch Construction in Action

```

<HTML>
<HEAD>
<TITLE>Switch Statement and Labeled Break</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
// build two product arrays, simulating two database tables
function product(name, price) {
    this.name = name
    this.price = price
}
var ICs = new Array()
ICs[0] = new product("Septium 900MHz", "$149")
ICs[1] = new product("Septium Pro 1.0GHz", "$249")
ICs[2] = new product("Octium BFD 750MHz", "$329")
var snacks = new Array
snacks[0] = new product("Rays Potato Chips", "$1.79")
snacks[1] = new product("Cheezey-ettes", "$1.59")
snacks[2] = new product("Tortilla Flats", "$2.29")

// lookup in the 'table' associated with the product
function getPrice(selector) {
    var chipName = selector.options[selector.selectedIndex].text
    var outField = document.forms[0].cost
    master:
        switch(selector.options[selector.selectedIndex].value) {
            case "ICs":
                for (var i = 0; i < ICs.length; i++) {
                    if (ICs[i].name == chipName) {
                        outField.value = ICs[i].price
                        break master
                    }
                }
                break

If you need this kind of functionality in your script but your audience is not all running level 4 or later browsers, see Listing 39-1 for ways to simulate the `switch` statement with `if . . . else` constructions.

Exception Handling

The subject of exception handling is relatively new to JavaScript. Formalized in Edition 3 of ECMA-262, parts of the official mechanism are implemented in IE5, with a more complete implementation in NN6. As you see in the rest of this chapter, both IE5+ and NN6 follow many of the same rules with respect to controlling execution paths (the primary subject of this chapter). But IE's departure from the ECMA-262 specification on some of the details can force scripters to take some extra steps to make exception handling work smoothly across browsers. More on that later. First, an overview of exception handling.

Exceptions and errors

If you've done any scripting, you are certainly aware of JavaScript errors, whether they be from syntax errors in your code, or what are known as *runtime* errors — errors that occur while scripts are processing information. Ideally, a program should be aware of when an error occurs and handle it as gracefully as possible. This self-healing can prevent lost data (usually not a big problem in Web applications) and prevent users from seeing the ugliness of error messages. In Chapter 16, you learn about the `onError` event handler (and `window.onerror` property), which were early attempts at letting scripts gain a level of control over runtime errors. This event-driven mechanism works on a global level (that is, in the `window` object) and processes every error that occurs throughout the page. This event handler ends up being used primarily as a last-ditch defense against displaying any error message to the user and is a long way from what programmers consider to be exception handling.

In the English language, the term “exception” can mean the same as something out of the ordinary, or something abnormal. This definition seems quite distant from the word “error,” which usually means a mistake. In the realm of programming languages, however, the two words tend to be used interchangeably, and the difference between the two depends primarily on one's point of view.

Consider, for example, a simple script whose job is to multiply numbers that the user enters into two text fields on the page. The script is supposed to display the results in a third text box. If the script contains no data entry validation, JavaScript will attempt to multiply whatever values are entered into the text boxes. If the user enters two numbers, JavaScript is smart enough to recognize that even though the `value` properties of the two input text fields are strings, the strings contain numbers that can be converted to number types for the proper multiplication. Without complaint, the product of the two numbers gets calculated and displayed into the results.

But what if the user types a letter into one of the text boxes? Again, without any entry validation in the script, JavaScript has a fixed way of responding to such a request: The result of the multiplication operation is the `NaN` (not a number) constant. If you are an untrained user, you have no idea what `NaN` means, but your experience with computers tells you that some kind of error has occurred. You may blame the computer or you may blame yourself.

To shift the point of view to the programmer, however, the script was designed to be run by a user who never makes a typing mistake, intentional or not. That, of course, is not very good programming practice. Users make mistakes. Therefore, anticipating user input that is not what would be expected is the programmer's job—input that is an exception to the rules your program wants to operate by. You must include some additional code that handles the exceptions gracefully so as to not confuse the user with unintelligible output and perhaps even help the user repair the input to get a result. This extra programming code handles the undesirable and erroneous input.

As it turns out, JavaScript and the W3C Document Object Model liberally mix terms of exception and error within the vocabulary used to handle exceptions. As you see shortly, an exception creates an *error object*, which contains information about the exception. It is safe to say that you can think of exceptions and errors as the same things.

The exception mechanism

Newcomers to JavaScript (or any programming environment, for that matter) may have a difficult time at first creating a mental model of how all this stuff runs within the context of the browser. It may be easy enough to understand how pages load and create object models, and how event handlers (or listeners in the W3C DOM terminology) cause script functions to run. But a lot of action also seems to be going on in the background. For example, the event object that is generated automatically with each event action (see Chapter 29) seems to sit “somewhere” while event handler functions run so that they can retrieve details about the event. After the functions finish their processing, the event object disappears, without even leaving behind a Cheshire Cat smile. Mysterious.

Browsers equipped for exception handling have more of this “stuff” running in the background, ready for your scripts when you need it. Because you have certainly viewed the details of at least one scripting error, you have already seen some of the exception handling mechanism that is built into browsers. If a script error occurs, the browser creates in its memory an error object, whose properties contain details about the error. The precise details (described later in this chapter) vary from one browser brand to the next, but what you see in the error details read-out is the default way the browser handles exceptions/errors. As browsers have

matured, their makers have gone to great lengths to tone down the intrusion of script errors. For example in NN4+, errors appear in a separate JavaScript Console window (which must be invoked in NN4 by typing `javascript:` into the Location field; or opened directly via the Tools menu in NN6), while users see only a message about the existence of an error in the statusbar. In IE4+ for Windows, the statusbar comes into play again, as the icon at the bottom-left corner turns into an alert icon: Double-clicking the icon displays more information about the error. IE/Mac users can turn off scripting error alerts altogether.

True exception handling, however, goes further than just displaying error messages. It also provides a uniform way to let scripts guard against unusual occurrences. Ideally, the mechanism makes sure that *all* runtime errors get funneled through the same mechanism to help simplify the scripting of exception handling. The mechanism is also designed to be used intentionally as a way for your own code to generate errors in a uniform way so that other parts of your scripts can handle them quietly and intelligently. In other words, you can use the exception handling mechanism as a kind of “back channel” to communicate from one part of your scripts to another.

The JavaScript exception handling mechanism is built around two groups of program execution statements. The first group consists of the `try-catch-finally` statement triumvirate; the second group is the single `throw` statement.

Using try-catch-finally constructions

The purpose of the `try-catch-finally` group of related statements is to provide a controlled environment in which script statements that may encounter runtime errors can run, such that if an exception occurs, your scripts can act upon the exception without alarming the rest of the browser’s error mechanisms. Each of the three statements precedes a block of code in the following syntax:

```
try {
    statements to run
}
catch (errorInfo) {
    statements to run if exception occurs in try block
}
finally {
    statements to run whether or not an exception occurred [optional]
}
```

Each `try` block must be mated with a `catch` and/or `finally` block at the same nesting level, with no intervening statements. For example, a function can have a one-level `try-catch` construction inside it as follows:

```
function myFunc() {
    try {
        statements
    }
    catch (e) {
        statements
    }
}
```

But if there were another `try` block nested one level deeper, a balancing `catch` or `finally` block would also have to be present at that deeper level:

```
function myFunc() {
  try {
    statements
    try {
      statements
    }
    catch (e) {
      statements
    }
  }
  catch (e) {
    statements
  }
}
```

The statements inside the `try` block include statements that you believe are capable of generating a runtime error because of user input errors, the failure of some page component to load, or a similar error. The presence of the `catch` block prevents errors from appearing in the browser’s regular script error reporting system (for example, the JavaScript Console of NN6).

An important term to know about exception handling of this type is *throw*. The convention is that when an operation or method call triggers an exception, it is said to “throw an exception.” For example, if a script statement attempts to invoke a method of a string object, but that method does not exist for the object (perhaps you mistyped the method name), JavaScript throws an exception. Exceptions have names associated with them—a name that sometimes, but not always, reveals important information about the exception. In the mistyped method example just cited, the name of that exception is a `TypeError` (yet more evidence of how “exception” and “error” become intertwined).

The JavaScript language (in IE5+ and NN6+) is not the only entity that can throw exceptions. The W3C DOM also defines categories of exceptions for DOM objects. For example, according to the Level 2 specification, the `appendChild()` method (see Chapter 15) can throw (or *raise*, in the W3C terminology) one of three exceptions:

Exception Name	When Thrown
HIERARCHY_REQUEST_ERR	If the current node is of a type that does not allow children of the type of the <i>newChild</i> node, or if the node to append is one of this node’s ancestors
WRONG_DOCUMENT_ERR	If <i>newChild</i> was created from a different document than the one that created the current node
NO_MODIFICATION_ALLOWED_ERR	If the current node is read-only

Because the `appendChild()` method is capable of throwing exceptions, a JavaScript statement that invokes this method should ideally be inside a `try` block.

If an exception is thrown, then script execution immediately jumps to the `catch` or `finally` block associated with the `try` block. Execution does not come back to the `try` block.

A `catch` block has special behavior. Its format looks similar to a function in a way, because the `catch` keyword is followed by a pair of parentheses and an arbitrary variable that is assigned a reference to the error object whose properties are filled by the browser when the exception occurs. One of the properties of that error object is the name of the error. Therefore, the code inside the `catch` block can examine the name of the error and perhaps include some branching code to take care of a variety of different errors that are caught.

To see how this construction may look in code, look at a hypothetical generic function whose job is to create a new element and append it to some other node. Both the type of element to be created and a reference to the parent node are passed as parameters. To take care of potential misuses of this function through the passage of improper parameter values, it includes extra error handling to treat all possible exceptions from the two DOM methods: `createElement()` and `appendChild()`. Such a function looks like Listing 39-7.

Listing 39-7: A Hypothetical try-catch Routine

```
// generic appender
function attachToEnd(theNode, newTag) {
    try {
        var newElem = document.createElement(newTag)
        theNode.appendChild(newElem)
    }
    catch (e) {
        switch (e.name) {
            case "INVALID_CHARACTER_ERR" :
                statements to handle this createElement() error
                break
            case "HIERARCHY_REQUEST_ERR" :
                statements to handle this appendChild() error
                break
            case "WRONG_DOCUMENT_ERR" :
                statements to handle this appendChild() error
                break
            case "NO_MODIFICATION_ALLOWED_ERR" :
                statements to handle this appendChild() error
                break
            default:
                statements to handle any other error
        }
        return false
    }
    return true
}
```

The single `catch` block in Listing 39-7 executes only if one of the statements in the `try` block throws an exception. The exceptions may be not only one of the four specific ones named in the `catch` block but also syntax or other errors that could occur inside the `try` block. That's why you have a last-ditch case to handle truly unexpected errors. Your job as scripter is to not only anticipate errors but also to provide clean ways for the exceptions to be handled, whether they be through judiciously worded alert dialog boxes or perhaps even some self-repair. For example, in the case of the invalid character error for `createElement()`, your script may attempt to salvage the data passed to the `attachToEnd()` function and reinvoke the method passing the `node` value as-is and the repaired value originally passed to `newTag`. If your repairs were successful, the `try` block would execute without error and carry on with the user's being completely unaware that a nasty problem had been averted.

A `finally` block contains code that always executes after a `try` block, whether or not the `try` block succeeds without throwing an error. Unlike the `catch` block, a `finally` block does not receive an error object as a parameter, so it operates very much in the dark about what transpires inside the `try` block. If you include both `catch` and `finally` blocks after a `try` block, the execution path depends on whether an exception is thrown. If no exception is thrown, the `finally` block executes after the last statement of the `try` block runs. But if the `try` block throws an exception, program execution runs first to the `catch` block. After all processing within the `catch` block finishes, the `finally` block executes. In development environments that give programmers complete control over resources, such as memory allocation, a `finally` block may be used to delete some temporary items generated in the `try` block, whether or not an exception occurs in the `try` block. Currently, JavaScript has less need for that kind of maintenance, but you should be aware of the program execution possibilities of the `finally` block in the `try-catch-finally` context.

Real-life exceptions

The example shown in Listing 39-6 is a bit idealized. The listing assumes that the browser dutifully reports every W3C DOM exception precisely as defined in the formal specification. Unfortunately, that's not how it is (yet) in browsers through IE5.5 and NN6. Both browsers implement additional error naming conventions and layers between actual DOM exceptions and what gets reported with the error object at the time of the exception.

If you think these discrepancies make cross-browser exception handling difficult, you're right. Even simple errors are reported differently among the two major browser brands and the W3C DOM specification. Until the browsers exhibit a greater unanimity in exception reporting, the smoothest development road will be for those scripters who have the luxury of writing for one of the browser platforms, such as IE5 for Windows or NN6.

That said, however, one aspect of exception handling can still be used in both IE5+ and NN6. You can take advantage of `try-catch` constructions to throw your own exceptions — a practice that is quite common in advanced programming environments.

Throwing Exceptions

The last exception handling keyword not covered yet — `throw` — makes it possible to utilize exception handling facilities for your own management of processes, such as data entry validation. At any point inside a `try` block, you can manually throw an exception that gets picked up by the associated `catch` block. The details of the specific exception are up to you.

Syntax for the `throw` statement is as follows:

```
throw value
```

The value you throw can be of any type, but good practice suggests that the value be an error object (described more fully later in this chapter). Whatever value you throw is assigned to the parameter of the `catch` block. Look at the following two examples. In the first, the value is a string message; in the second, the value is an error object.

Listing 39-8 presents one input text box for a number between 1 and 5. Clicking a button looks up a corresponding letter in an array and displays the letter in a second text box. The lookup script has two simple data validation routines to make sure the entry is a number and is in the desired range. Error checking here is done manually by script. If either of the error conditions occurs, `throw` statements force execution to jump to the `catch` block. The `catch` block assigns the incoming string parameter to the variable `e`. The design here assumes that the message being passed is text for an alert dialog box. Not only does a single `catch` block take care of both error conditions (and conceivably any others to be added later), but the `catch` block runs within the same variable scope as the function, so that it can use the reference to the input text box to focus and select the input text if there is an error.

Listing 39-8: Throwing String Exceptions

```
<HTML>
<HEAD>
<TITLE>Throwing a String Exception</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var letters = new Array("A","B","C","D","E")
function getLetter(fld) {
    try {
        var inp = parseInt(fld.value, 10)
        if (isNaN(inp)) {
            throw "Entry was not a number."
        }
        if (inp < 1 || inp > 5) {
            throw "Enter only 1 through 5."
        }
        fld.form.output.value = letters[inp]
    }
    catch (e) {
        alert(e)
        fld.form.output.value = ""
    }
}
```

Continued

Listing 39-8 (continued)

```

        fld.focus()
        fld.select()
    }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Throwing a String Exception</H1>
<HR>
<FORM>
Enter a number from 1 to 5:
<INPUT TYPE="text" NAME="input" SIZE=5>
<INPUT TYPE="button" VALUE="Get Letter" onClick=getLetter(this.form.input)>
Matching Letter is:<INPUT TYPE="text" NAME="output" SIZE=5>
</FORM>
</BODY>
</HTML>

```

The flaw with Listing 39-8 is that if some other kind of exception were thrown inside the `try` block, the value passed to the `catch` block would be an error object, not a string. The alert dialog box displayed to the user would be meaningless. Therefore, it is better to be uniform in your `throw-catch` constructions and pass an error object.

Listing 39-9 is an updated version of Listing 39-8, demonstrating how to create an error object that gets sent to the `catch` block via `throw` statements. The one glitch in generating an error object comes in IE5 and IE5.5. The ECMA-262 standard allows a script statement to set the `message` property of an error object to directly by passing a string as the parameter to the new `Error()` constructor. This is how NN6 works. But the error object in IE5 does not have the `message` property at all, and in IE5.5, the parameter is not assigned to the `message` property. Therefore, Listing 39-9 contains a separate utility function (`getErrorObj()`) that fills the gap when an error object does not have the `message` property to begin with or doesn't have the property set automatically. If a future version of IE adopts the ECMA standard way, then the extra branch is avoided, just as it is for NN6.

Listing 39-9: Throwing an Error Object Exception

```

<HTML>
<HEAD>
<TITLE>Throwing an Error Object Exception</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var letters = new Array("A","B","C","D","E")
function getErrorObj(msg) {
    var err = new Error(msg)
    // take care of IE5/5.5
    if (!err.message) {

```

```

        err.message = msg
    }
    return err
}
function getLetter(fld) {
    try {
        var inp = parseInt(fld.value, 10)
        if (isNaN(inp)) {
            throw getErrorObj("Entry was not a number.")
        }
        if (inp < 1 || inp > 5) {
            throw getErrorObj("Enter only 1 through 5.")
        }
        fld.form.output.value = letters[inp]
    }
    catch (e) {
        alert(e.message)
        fld.form.output.value = ""
        fld.focus()
        fld.select()
    }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Throwing an Error Object Exception</H1>
<HR>
<FORM>
Enter a number from 1 to 5:
<INPUT TYPE="text" NAME="input" SIZE=5>
<INPUT TYPE="button" VALUE="Get Letter" onClick=getLetter(this.form.input)>
Matching Letter is:<INPUT TYPE="text" NAME="output" SIZE=5>
</FORM>
</BODY>
</HTML>

```

The only difference to the `catch` block is that it now reads the `message` property of the incoming error object. This means that if some other exception is thrown inside the `try` block, the browser-generated message will be displayed in the alert dialog box.

In truth, however, the job really isn't complete. In all likelihood, if a browser-generated exception is thrown, the message in the alert dialog box won't mean much to the user. The error message will probably be some kind of syntax or type error—the kind of meaningless error message you often get from your favorite operating system. A better design is to branch the `catch` block so that “intentional” exceptions thrown by your code are handled through the alert dialog box messages you've put there, but other types are treated differently. To accomplish this, you can take over one of the other properties of the error object—`name`—so that your `catch` block treats your custom messages separately.

In Listing 39-10, the `getErrorObj()` function adds a custom value to the `name` property of the newly created error object. The name you assign can be any name, but you want to avoid exception names used by JavaScript or the DOM. Even if you don't know what all of those are, you can probably conjure up a suitably unique name for your error. Down in the `catch` block, a `switch` construction branches to treat the two classes of errors differently. Notice that because IE5's error object does not have a `name` property, the `switch` expression (`e.name`) evaluates to `undefined`, which forces the default case to execute whenever a native exception is thrown (and you have to be careful about which error object properties you use in the default case statements). In this simplified example, about the only possible problem other than the ones being trapped for explicitly in the `try` block would be some corruption to the page during downloading. Therefore, for this example, the branch for all other errors simply asks that the user reload the page and try again. The point is, however, that you can have as many classifications of custom and system errors as you want and handle them in a single `catch` block accordingly.

Listing 39-10: A Custom Object Exception

```
<HTML>
<HEAD>
<TITLE>Throwing a Custom Error Object Exception</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var letters = new Array("A","B","C","D","E")
function getErrorObj(msg) {
    var err = new Error(msg)
    // take care of IE5/5.5
    if (!err.message) {
        err.message = msg
    }
    err.name = "MY_ERROR"
    return err
}
function getLetter(fld) {
    try {
        var inp = parseInt(fld.value, 10)
        if (isNaN(inp)) {
            throw getErrorObj("Entry was not a number.")
        }
        if (inp < 1 || inp > 5) {
            throw getErrorObj("Enter only 1 through 5.")
        }
        fld.form.output.value = letters[inp]
    }
    catch (e) {
        switch (e.name) {
            case "MY_ERROR" :
                alert(e.message)
                fld.form.output.value = ""
                fld.focus()
                fld.select()
        }
    }
}
```

```

        break
    default :
        alert("Reload the page and try again.")
    }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Throwing a Custom Error Object Exception</H1>
<HR>
<FORM>
Enter a number from 1 to 5:
<INPUT TYPE="text" NAME="input" SIZE=5>
<INPUT TYPE="button" VALUE="Get Letter" onClick=getLetter(this.form.input)>
Matching Letter is:<INPUT TYPE="text" NAME="output" SIZE=5>
</FORM>
</BODY>
</HTML>

```

If you want to see how the alternative branch of Listing 39-10 looks, copy the listing file from the CD-ROM to your hard disk and modify the last line of the `try` block so that one of the letters is dropped from the name of the array:

```
fld.form.output.value = letter[inp]
```

This may simulate the faulty loading of the page. If you enter one of the allowable values, the reload alert appears, rather than the actual message of the error object: letter is undefined. Your users will thank you.

All that's left now on this subject are the details on the error object.

Error Object

Properties	Methods
<code>Error.prototype</code>	<code>errorObject.toString()</code>
<code>errorObject.constructor</code>	
<code>errorObject.description</code>	
<code>errorObject.filename</code>	
<code>errorObject.lineNumber</code>	
<code>errorObject.message</code>	
<code>errorObject.name</code>	
<code>errorObject.number</code>	

Syntax

Creating an error object:

```
var myError = new Error("message")
var myError = Error("message")
```

Accessing static Error object property:

```
Error.property
```

Accessing error object properties and methods:

```
errorObject.property | method([parameters])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓				✓	✓

About this object

An error object instance is created whenever an exception is thrown or when you invoke either of the constructor formats for creating an error object. Properties of the error object instance contain information about the nature of the error so that `catch` blocks can inspect the error and process error handling accordingly.

IE5 implemented an error object in advance of the ECMA-262 formal error object, and the IE5 version ends up having its own set of properties that are not part of the ECMA standard. Those proprietary properties are still part of IE5.5, which includes the ECMA properties as well. NN6, on the other hand, starts with the ECMA properties and adds two proprietary properties of its own. The browser uses these additional properties in its own script error reporting. The unfortunate bottom line for cross-browser developers is that no properties in common among all browsers support the error object. However, two common denominators (`name` and `message`) are between IE5.5 and NN6.

As described earlier in this chapter, you are encouraged to create an error object whenever you use the `throw` statement for your own error control. See the discussion surrounding Listing 39-9 about handling missing properties in IE.

Properties

constructor

See `string.constructor` (Chapter 34).

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

The `description` property contains a descriptive string that provides some level of detail about the error. For errors thrown by the browser, the description is the same text that appears in the script error dialog box in IE. Although this property continues to be supported, the `message` property in IE5.5 and NN6 is preferred.

Related Items: `message` property.

fileName lineNumber

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

The NN6 browser uses the `fileName` and `lineNumber` properties of an error object for its own internal script error processing—these values appear as part of the error messages that are listed in the JavaScript Console. The `fileName` is the URL of the document causing the error; the `lineNumber` is the source code line number of the statement that threw the exception. These properties are exposed to JavaScript, as well, so that your error processing may use this information if it is meaningful to your application.

Both of these properties (along with the `message` property) have been in the Navigator vernacular since NN3. See the discussion of the `window.error` property in Chapter 16 for further ideas on how to use this information for bug reporting from users.

Related Items: `window.error` property.

message

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `message` property contains a descriptive string that provides some level of detail about the error. For errors thrown by the browser, the message is the same text that appears in the script error dialog box in IE and the JavaScript Console in NN6. By and large, these messages are more meaningful to scripters than to users. Unfortunately, there are no standards for the wording of a message for a given error. Therefore, it is hazardous at best to use the message content in a `catch` block as a means of branching to handle particular kinds of errors. You may get by with this approach if you are developing for a single browser platform, but you have no assurances that the text of a message for a particular exception may not change in future browser versions.

Custom messages for errors that your code explicitly throws can be in user-friendly language if you intend to display such messages to users. See Listings 39-8 through 39-10 for examples of this usage.

Related Items: `description` property.

name

Value: String

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `name` property generally contains a word that identifies the type of error that has been thrown. The most general kind of error (and the one that is created via the new `Error()` constructor) has a `name` property of `Error`. But JavaScript errors can be of several varieties: `EvalError`, `RangeError`, `ReferenceError`, `SyntaxError`, `TypeError`, and `URIError`. Some of these error types are not necessarily intended for exposure to scripters (they're used primarily in the inner workings of the JavaScript engine), but some browsers do expose them. Unfortunately, there are some discrepancies as to the specific name supplied to this property for script errors.

When JavaScript is being used in a browser environment that employs the W3C DOM, some DOM exception types are returned via the `name` property. But browsers frequently insert their own error types for this property, and, as is common in this department, little uniformity exists among browser brands.

For custom exceptions that your code explicitly throws, you can assign names as you want. As shown in Listings 39-9 and 39-10, this information can assist a `catch` block in handling multiple categories of errors.

Related Items: `message` property.

number

Value: Number

Read/Write

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

IE5+ assigns unique numbers to each error description or message. The `number` property, however, is problematical. While Microsoft documents a sequence of syntax and runtime errors and their numbers, in practice, IE browsers do not report the numbers shown in Microsoft's own documentation. This is unfortunate, because the `number` can be a language-independent way of branching `catch` block code based on the error number, rather than the description or message. And,

because the `number` property was born at the same time as the `description` property (now superseded by the `message` property), it is unknown how reliable the number values (if you can figure them out) will be going forward.

Related Items: `description` property.

Methods

`toString()`

Returns: `String` (see text).

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓				✓	✓

The `toString()` method for an error object should return a string description of the error. In IE5 and 5.5, however, the method returns a reference to the very same error object. In NN6, the method returns the `message` property string, preceded by the string `Error:` (with a space after the colon). Most typically, if you want to retrieve a human-readable expression of an error object, read its `message` (or, in IE5, `description`) property.

Related Items: `message` property.

CHAPTER

JavaScript Operators

JavaScript is rich in *operators*: words and symbols in expressions that perform operations on one or two values to arrive at another value. Any value on which an operator performs some action is called an *operand*. An expression may contain one operand and one operator (called a *unary operator*) or two operands separated by one operator (called a *binary operator*). Many of the same symbols are used in a variety of operators. The combination and order of those symbols are what distinguish their powers.

Note

The vast majority of JavaScript operators have been in the language since the very beginning. But, as you may expect from an evolving language, some new entries have been added to the lexicon. In the rest of this chapter, compatibility charts typically govern an entire category of operator. If there are version anomalies for a particular operator within a category, they are covered in the text.

Operator Categories

To help you grasp the range of JavaScript operators, I group them into seven categories. I assign a wholly untraditional name to the second group — but a name that I believe better identifies its purpose in the language. Table 40-1 shows the operator types.

Table 40-1: JavaScript Operator Categories

Type	What It Does
Comparison	Compares the values of two operands, deriving a result of either true or false (used extensively in condition statements for <code>if...else</code> and <code>for</code> loop constructions)

Continued

In This Chapter

Understanding operator categories

Exploring the role of operators in script statements

Recognizing operator precedence

Table 40-1 (continued)

<i>Type</i>	<i>What It Does</i>
Connubial	Joins together two operands to produce a single value that is a result of an arithmetical or other operation on the two
Assignment	Stuffs the value of the expression of the right-hand operand into a variable name on the left-hand side, sometimes with minor modification, as determined by the operator symbol
Boolean	Performs Boolean arithmetic on one or two Boolean operands
Bitwise	Performs arithmetic or column-shifting actions on the binary (base-2) representations of two operands
Object	Helps scripts examine the heritage and capabilities of a particular object before they need to invoke the object and its properties or methods
Miscellaneous	A handful of operators that have special behaviors

Any expression that contains an operator evaluates to a value of some kind. Sometimes the operator changes the value of one of the operands; other times the result is a new value. Even this simple expression

```
5 + 5
```

shows two integer operands joined by the addition operator. This expression evaluates to 10. The operator is what provides the instruction for JavaScript to follow in its never-ending drive to evaluate every expression in a script.

Doing an equality comparison on two operands that, on the surface, look very different is not at all uncommon. JavaScript doesn't care what the operands look like—only how they evaluate. Two very dissimilar-looking values can, in fact, be identical when they are evaluated. Thus, an expression that compares the equality of two values, such as

```
fred == 25
```

does, in fact, evaluate to `true` if the variable `fred` has the number 25 stored in it from an earlier statement.

Comparison Operators

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Any time you compare two values in JavaScript, the result is a Boolean `true` or `false` value. You have a wide selection of comparison operators to choose from,

depending on the kind of test you want to apply to the two operands. Table 40-2 lists all comparison operators.

Table 40-2: JavaScript Comparison Operators

<i>Syntax</i>	<i>Name</i>	<i>Operand Types</i>	<i>Results</i>
==	Equals	All	Boolean
!=	Does not equal	All	Boolean
===	Strictly equals	All	Boolean (IE4+, NN4+)
!==	Strictly does not equal	All	Boolean (IE4+, NN4+)
>	Is greater than	All	Boolean
>=	Is greater than or equal to	All	Boolean
<	Is less than	All	Boolean
<=	Is less than or equal to	All	Boolean

For numeric values, the results are the same as those you'd expect from your high school algebra class. Some examples follow, including some that may not be obvious.

```
10 == 10           // true
10 == 10.0        // true
9 != 10           // true
9 > 10            // false
9.99 <= 9.98     // false
```

Strings can also be compared on all of these levels:

```
"Fred" == "Fred"  // true
"Fred" == "fred"  // false
"Fred" > "fred"   // false
"Fran" < "Fred"   // true
```

To calculate string comparisons, JavaScript converts each character of a string to its ASCII value. Each letter, beginning with the first of the left-hand operator, is compared to the corresponding letter in the right-hand operator. With ASCII values for uppercase letters being less than those of their lowercase counterparts, an uppercase letter evaluates to being less than its lowercase equivalent. JavaScript takes case-sensitivity very seriously.

Values for comparison can also come from object properties or values passed to functions from event handlers or other functions. A common string comparison used in data-entry validation is the one that sees if the string has anything in it:

```
form.entry.value != "" // true if something is in the field
```

Equality of Disparate Data Types

For all versions of JavaScript before 1.2, when your script tries to compare string values consisting of numerals and real numbers (for example, "123" == 123 or "123" != 123), JavaScript anticipates that you want to compare apples to apples. Internally it does some data type conversion that does not affect the data type of the original values (for example, if the values are in variables). But the entire situation is more complex, because other data types, such as objects, need to be dealt with. Therefore, prior to JavaScript 1.2, the rules of comparison are as shown in Table 40-3.

Table 40-3: Equality Comparisons for JavaScript 1.0 and 1.1

<i>Operand A</i>	<i>Operand B</i>	<i>Internal Comparison Treatment</i>
Object reference	Object reference	Compare object reference evaluations
Any data type	Null	Convert nonnull to its object type and compare against null
Object reference	String	Convert object to string and compare strings
String	Number	Convert string to number and compare numbers

The logic to what goes on in equality comparisons from Table 40-3 requires a lot of forethought on the scripter's part, because you have to be very conscious of the particular way data types may or may not be converted for equality evaluation (even though the values themselves are not converted). In this situation, supplying the proper conversion where necessary in the comparison statement is best. This ensures that what you want to compare—for example, the string versions of two values or the number versions of two values—is compared, rather than leaving the conversion up to JavaScript.

Backward compatible conversion from a number to string entails concatenating an empty string to a number:

```
var a = "09"
var b = 9
a == "" + b // result: false, because "09" does not equal "9"
```

For converting strings to numbers, you have numerous possibilities. The simplest is subtracting zero from a numeric string:

```
var a = "09"
var b = 9
a-0 == b // result: true because number 9 equals number 9
```

You can also use the `parseInt()` and `parseFloat()` functions to convert strings to numbers:

```
var a = "09"
var b = 9
parseInt(a, 10) == b // result: true because number 9 equals number 9
```

To clear up the ambiguity of JavaScript's equality internal conversions, JavaScript 1.2 in NN4 and IE4 adds two more operators to force the equality comparison to be extremely literal in its comparison. The strictly equals (`===`) and strictly does not equal (`!==`) operators compare both the data type and value. The only time the `===` operator returns true is if the two operands are of the same data type (for example, both are numbers) and the same value. Therefore, no number is ever automatically equal to a string version of that same number. Data and object types must match before their values are compared.

JavaScript 1.2 also provides some convenient global functions for converting strings to numbers and vice versa: `String()` and `Number()`. To demonstrate these methods, the following examples use the `typeof` operator to show the data type of expressions using these functions:

```
typeof 9 // result: number
typeof String(9) // result: string
typeof "9" // result: string
typeof Number("9") // result: number
```

None of these functions alters the data type of the value being converted. But the value of the function is what gets compared in an equality comparison:

```
var a = "09"
var b = 9
a == String(b) // result: false, because "09" does not equal "9"
typeof b // result: still a number
Number(a) == b // result: true, because 9 equals 9
typeof a // result: still a string
```

This discussion should impress upon you the importance of considering data types when testing the equality of two values.

Connubial Operators

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Connubial operators is my terminology for those operators that join two operands to yield a value related to the operands. Table 40-4 lists the connubial operators in JavaScript.

Table 40-4: JavaScript Connubial Operators

<i>Syntax</i>	<i>Name</i>	<i>Operand Types</i>	<i>Results</i>
+	Plus	Integer, float, string	Integer, float, string
-	Minus	Integer, float	Integer, float
*	Multiply	Integer, float	Integer, float
/	Divide	Integer, float	Integer, float
%	Modulo	Integer, float	Integer, float
++	Increment	Integer, float	Integer, float
--	Decrement	Integer, float	Integer, float
+val	Positive	Integer, float, string	Integer, float
-val	Negation	Integer, float, string	Integer, float

The four basic arithmetic operators for numbers are straightforward. The plus operator also works on strings to join them together, as in

```
"Howdy " + "Doody" // result = "Howdy Doody"
```

In object-oriented programming terminology, the plus sign is considered *overloaded*, meaning that it performs a different action depending on its context. Remember, too, that string concatenation does not do anything on its own to monitor or insert spaces between words. In the preceding example, the space between the names is part of the first string.

Modulo arithmetic is helpful for those times when you want to know if one number divides evenly into another. You used it in an example in Chapter 39 to figure out if a particular year was a leap year. Although some other leap year considerations exist for the turn of each century, the math in the example simply checked whether the year was evenly divisible by four. The result of the modulo math is the remainder of division of the two values: When the remainder is 0, one divides evenly into the other. Here are some samples of years evenly divisible by four:

```
2002 % 4 // result = 2
2003 % 4 // result = 3
2004 % 4 // result = 0 (Bingo! Leap year!)
```

Thus, I used this modulo operator in a condition statement of an `if . . . else` structure:

```
var howMany = 0
today = new Date()
var theYear = today.getYear()
if (theYear % 4 == 0) {
    howMany = 29
} else {
    howMany = 28
}
```

Some other languages offer an operator that results in the integer part of a division problem solution: integral division, or `div`. Although JavaScript does not have an explicit operator for this behavior, you can recreate it reliably if you know that your operands are always positive numbers. Use the `Math.floor()` or `Math.ceil()` methods with the division operator, as in

```
Math.floor(4/3)    // result = 1
```

In this example, `Math.floor()` works only with values greater than or equal to 0; `Math.ceil()` works with values less than 0.

The increment operator (`++`) is a *unary* operator (only one operand) and displays two different behaviors, depending on the side of the operand on which the symbols lie. Both the increment and decrement (`--`) operators can be used in conjunction with assignment operators, which I cover next.

As its name implies, the increment operator increases the value of its operand by one. But in an assignment statement, you have to pay close attention to precisely when that increase takes place. An assignment statement stuffs the value of the right operand into a variable on the left. If the `++` operator is located in front of the right operand (prefix), the right operand is incremented before the value is assigned to the variable; if the `++` operator is located after the right operand (postfix), the previous value of the operand is sent to the variable before the value is incremented. Follow this sequence to get a feel for these two behaviors:

```
var a = 10    // initialize a to 10
var z = 0     // initialize z to zero
z = a        // a = 10, so z = 10
z = ++a      // a becomes 11 before assignment, so a = 11 and z becomes 11
z = a++      // a is still 11 before assignment, so z = 11; then a becomes 12
z = a++      // a is still 12 before assignment, so z = 12; then a becomes 13
```

The decrement operator behaves the same way, except that the value of the operand decreases by one. Increment and decrement operators are used most often with loop counters in `for` and `while` loops. The simpler `++` or `--` symbology is more compact than reassigning a value by adding 1 to it (such as, `z = z + 1` or `z -= 1`). Because these are unary operators, you can use the increment and decrement operators without an assignment statement to adjust the value of a counting variable within a loop:

```
function doNothing() {
    var i = 1
    while (i < 20) {
        ++i
    }
    alert(i) // breaks out at i = 20
}
```

The last pair of connubial operators are also unary operators (operating on one operand). Both the positive and negation operators can be used as shortcuts to the `Number()` global function, converting a string operand consisting of number characters to a number data type. The string operand is not changed, but the operation returns a value of the number type, as shown in the following sequence:

```
var a = "123"
var b = +a    // b is now 123
```

```
typeof a // result: string
typeof b // result: number
```

The negation operator (*-val*) has additional power. By placing a minus sign in front of any numeric value (no space between the symbol and the value), you instruct JavaScript to evaluate a positive value as its corresponding negative value, and vice versa. The operator does not change the operand's value, but the expression returns the modified value. The following example provides a sequence of statements to demonstrate:

```
var x = 2
var y = 8
var z = -x // z equals -2, but x still equals 2
z = -(x + y) // z equals -10, but x still equals 2 and y equals 8
z = -x + y // z equals 6, but x still equals 2 and y equals 8
```

To negate a Boolean value, see the Not (!) operator in the discussion of Boolean operators.

Assignment Operators

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Assignment statements are among the most common statements you write in your JavaScript scripts. These statements appear everywhere you copy a value or the results of an expression into a variable for further manipulation of that value.

You assign values to variables for many reasons, even though you could probably use the original values or expressions several times throughout a script. Here is a sampling of reasons why you should assign values to variables:

- ♦ Variable names are usually shorter
- ♦ Variable names can be more descriptive
- ♦ You may need to preserve the original value for later in the script
- ♦ The original value is a property that cannot be changed
- ♦ Invoking the same method several times in a script is not efficient

Newcomers to scripting often overlook the last reason. For instance, if a script is writing HTML to a new document, it's more efficient to assemble the string of large chunks of the page into one variable before invoking the `document.write()` method to send that text to the document. This approach is more efficient than literally sending out one line of HTML at a time with multiple `document.writeln()` method statements. Table 40-5 shows the range of assignment operators in JavaScript.

Table 40-5: JavaScript Assignment Operators

<i>Syntax</i>	<i>Name</i>	<i>Example</i>	<i>Means</i>
=	Equals	x = y	x = y
+=	Add by value	x += y	x = x + y
-=	Subtract by value	x -= y	x = x - y
*=	Multiply by value	x *= y	x = x * y
/=	Divide by value	x /= y	x = x / y
%=	Modulo by value	x %= y	x = x % y
<<=	Left shift by value	x <<= y	x = x << y
>=	Right shift by value	x >= y	x = x > y
>>=	Zero fill by value	x >>= y	x = x >> y
>>>=	Right shift by value	x >>>= y	x = x >>> y
&=	Bitwise AND by value	x &= y	x = x & y
=	Bitwise OR by value	x = y	x = x y
^=	Bitwise XOR by value	x ^= y	x = x ^ y

As clearly demonstrated in the top group (see “Bitwise Operators” later in the chapter for information on the bottom group), assignment operators beyond the simple equals sign can save some characters in your typing, especially when you have a series of values that you’re trying to bring together in subsequent statements. You’ve seen plenty of examples in previous chapters, where you used the add-by-value operator (+=) to work wonders with strings as you assemble a long string variable that you eventually send to a `document.write()` method. Look at this variation of a segment of Listing 37-3, where you could use JavaScript to create the HTML content of a SELECT element on the fly:

```
var elem = "" // start assembling next part of page and form
elem += "<P>Select a regional office: "
elem += "<SELECT NAME='offices' onChange='getData(this.form)'"
// build options list from array office names
for (var i = 0; i < regionalOffices.length; i++) {
    elem += "<OPTION"           // OPTION tags
    if (i == 0) {             // pre-select first item in list
        elem += " SELECTED"
    }
    elem += ">" + regionalOffices[i]
}
elem += "</SELECT></P>" // close SELECT item tag
document.write(elem)     // write element to the page
```

The script segment starts with a plain equals assignment operator to initialize the `elem` variable as an empty string. In many of the succeeding lines, you use the

add-by-value operator to tack additional string values onto whatever is in the `elem` variable at the time. Without the add-by-value operator, you are forced to use the plain equals assignment operator for each line of code to concatenate new string data to the existing string data. In that case, the first few lines of code look as shown:

```
var elem = "" // start assembling next part of page and form
elem = elem + "<P>Select a regional office: "
elem = elem + "<SELECT NAME='offices' onChange='getData(this.form)'">"
```

Within the `for` loop, the repetition of `elem +` makes the code very difficult to read, trace, and maintain. These enhanced assignment operators are excellent shortcuts that you should use at every turn.

Boolean Operators

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Because a great deal of programming involves logic, it is no accident that the arithmetic of the logic world plays an important role. You've already seen dozens of instances where programs make all kinds of decisions based on whether a statement or expression is the Boolean value `true` or `false`. What you haven't seen much of yet is how to combine multiple Boolean values and expressions—a quality that scripts with slightly above average complexity may need to have in them.

In the various condition expressions required throughout JavaScript (such as in an `if` construction), the condition that the program must test for may be more complicated than, say, whether a variable value is greater than a certain fixed value or whether a field is not empty. Look at the case of validating a text field entry for whether the entry contains all the numbers that your script may want. Without some magical JavaScript function to tell you whether or not a string consists of all numbers, you have to break apart the entry character by character and examine whether each character falls within the range of 0 through 9. But that examination actually comprises two tests: You can test for any character whose ASCII value is less than 0 or greater than 9. Alternatively, you can test whether the character is greater than or equal to 0 and is less than or equal to 9. What you need is the bottom-line evaluation of both tests.

Boolean math

That's where the wonder of Boolean math comes into play. With just two values—`true` and `false`—you can assemble a string of expressions that yield Boolean results and then let Boolean arithmetic figure out whether the bottom line is `true` or `false`.

But you don't add or subtract Boolean values the same way you add or subtract numbers. Instead, you use one of three JavaScript Boolean operators at your disposal. Table 40-6 shows the three operator symbols. In case you're unfamiliar with the characters in the table, the symbols for the Or operator are created by typing Shift-backslash.

Table 40-6: JavaScript Boolean Operators

<i>Syntax</i>	<i>Name</i>	<i>Operands</i>	<i>Results</i>
&&	And	Boolean	Boolean
	Or	Boolean	Boolean
!	Not	One Boolean	Boolean

Using Boolean operators with Boolean operands gets tricky if you're not used to it, so I have you start with the simplest Boolean operator: Not. This operator requires only one operand. The Not operator precedes any Boolean value to switch it back to the opposite value (from true to false, or from false to true). For instance:

```
!true           // result = false
!(10 > 5)       // result = false
!(10 < 5)       // result = true
!(document.title == "Flintstones") // result = true
```

As shown here, enclosing the operand of a Not expression inside parentheses is always a good idea. This forces JavaScript to evaluate the expression inside the parentheses before flipping it around with the Not operator.

The And (&&) operator joins two Boolean values to reach a true or false value based on the results of both values. This brings up something called a *truth table*, which helps you visualize all the possible outcomes for each value of an operand. Table 40-7 is a truth table for the And operator.

Table 40-7: Truth Table for the And Operator

<i>Left Operand</i>	<i>And Operator</i>	<i>Right Operand</i>	<i>Result</i>
True	&&	True	True
True	&&	False	False
False	&&	True	False
False	&&	False	False

Only one condition yields a true result: Both operands must evaluate to true. Which side of the operator a true or false value lives doesn't matter. Here are examples of each possibility:

```
5 > 1 && 50 > 10 // result = true
5 > 1 && 50 < 10 // result = false
5 < 1 && 50 > 10 // result = false
5 < 1 && 50 < 10 // result = false
```

In contrast, the Or (`|`) operator is more lenient about what it evaluates to `true`. The reason is that if one or the other (or both) operands is `true`, the operation returns `true`. The Or operator's truth table is shown in Table 40-8.

Table 40-8: Truth Table for the Or Operator

<i>Left Operand</i>	<i>Or Operator</i>	<i>Right Operand</i>	<i>Result</i>
True	<code> </code>	True	True
True	<code> </code>	False	True
False	<code> </code>	True	True
False	<code> </code>	False	False

Therefore, if a `true` value exists on either side of the operator, a `true` value is the result. Take the previous examples and swap the And operators with Or operators so that you can see the Or operator's impact on the results:

```
5 > 1 || 50 > 10    // result = true
5 > 1 || 50 < 10    // result = true
5 < 1 || 50 > 10    // result = true
5 < 1 || 50 < 10    // result = false
```

Only when both operands are `false` does the Or operator return `false`.

Boolean operators at work

Applying Boolean operators to JavaScript the first time just takes a little time and some sketches on a pad of paper to help you figure out the logic of the expressions. Earlier I talked about using a Boolean operator to see whether a character fell within a range of ASCII values for data-entry validation. Listing 40-1 (not on the CD-ROM) is a function discussed in more depth in Chapter 43. This function accepts any string and sees whether each character of the string has an ASCII value less than 0 or greater than 9—meaning that the input string is not a number.

Listing 40-1: Is the Input String a Number?

```
function isNumber(inputStr) {
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.substring(i, i + 1)
        if (oneChar < "0" || oneChar > "9") {
            alert("Please make sure entries are numerals only.")
            return false
        }
    }
    return true
}
```

Combining a number of JavaScript powers to read individual characters (substrings) from a string object within a for loop, the statement that you're interested in is the condition of the if construction:

```
(oneChar < "0" || oneChar > "9")
```

In one condition statement, you use the Or operator to test for both possibilities. If you check the Or truth table (Table 40-8), you see that this expression returns true if either one or both tests returns true. If that happens, the rest of the function alerts the user about the problem and returns a false value to the calling statement. Only if both tests within this condition evaluate to false for all characters of the string does the function return a true value.

From the simple Or operator, I go to the extreme, where the function checks—in one condition statement—whether a number falls within several numeric ranges. The script in Listing 40-2 comes from the array lookup application in Chapter 50, in which a user enters the first three digits of a U.S. Social Security number.

Listing 40-2: Is a Number within Discontiguous Ranges?

```
// function to determine if value is in acceptable range for this application
function inRange(inputStr) {
    num = parseInt(inputStr)
    if (num < 1 || (num > 586 && num < 596) || (num > 599 && num < 700) || num >
728) {
        alert("Sorry, the number you entered is not part of our database. Try
another three-digit number.")
        return false
    }
    return true
}
```

By the time this function is called, the user's data entry has been validated enough for JavaScript to know that the entry is a number. Now the function must check whether the number falls outside of the various ranges for which the application contains matching data. The conditions that the function tests here are whether the number is

- ♦ Less than 1
- ♦ Greater than 586 and less than 596 (using the And operator)
- ♦ Greater than 599 and less than 700 (using the And operator)
- ♦ Greater than 728

Each of these tests is joined by an Or operator. Therefore, if any one of these conditions proves true, the whole if condition is true, and the user is alerted accordingly.

The alternative to combining so many Boolean expressions in one condition statement would be to nest a series of if constructions. But such a construction requires not only a great deal more code but also much repetition of the alert dialog

box message for each condition that could possibly fail. The combined Boolean condition is, by far, the best way to go.

Bitwise Operators

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

For scripters, bitwise operations are an advanced subject. Unless you're dealing with external processes on CGIs or the connection to Java applets, it's unlikely that you will use bitwise operators. Experienced programmers who concern themselves with more specific data types (such as long integers) are quite comfortable in this arena, so I simply provide an explanation of JavaScript capabilities. Table 40-9 lists JavaScript bitwise operators.

Table 40-9: JavaScript's Bitwise Operators

<i>Operator</i>	<i>Name</i>	<i>Left Operand</i>	<i>Right Operand</i>
&	Bitwise And	Integer value	Integer value
	Bitwise Or	Integer value	Integer value
^	Bitwise XOR	Integer value	Integer value
~	Bitwise Not	(None)	Integer value
<<	Left shift	Integer value	Shift amount
>>	Right shift	Integer value	Shift amount
>>>	Zero fill right shift	Integer value	Shift amount

The numeric value operands can appear in any of the JavaScript language's three numeric literal bases (decimal, octal, or hexadecimal). As soon as the operator has an operand, the value is converted to binary representation (32 bits long). For the first three bitwise operations, the individual bits of one operand are compared with their counterparts in the other operand. The resulting value for each bit depends on the operator:

- ♦ **Bitwise And:** 1 if both digits are 1
- ♦ **Bitwise Or:** 1 if either digit is 1
- ♦ **Bitwise Exclusive Or:** 1 if only one digit is a 1

Bitwise Not, a unary operator, inverts the value of every bit in the single operand. The bitwise shift operators operate on a single operand. The second operand specifies the number of positions to shift the value's binary digits in the

direction of the arrows of the operator symbols. For example, the left shift (`<<`) operator has the following effect:

```
4 << 2 // result = 16
```

The reason for this shifting is that the binary representation for decimal 4 is 00000100 (to eight digits, anyway). The left shift operator instructs JavaScript to shift all digits two places to the left, giving the binary result 00010000, which converts to 16 in decimal format. If you're interested in experimenting with these operators, use The Evaluator (Chapter 13) to evaluate sample expressions for yourself. More advanced books on C and C++ programming are also of help.

Object Operators

The next group of operators concern themselves with objects (including native JavaScript, DOM, and custom objects) and data types. Most of these have been implemented after the earliest JavaScript browsers, so each one has its own compatibility rating.

delete

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Array objects do not contain a method to remove an element from the collection, nor do custom objects offer a method to remove a property. You can always empty the data in an array item or property by setting its value to an empty string or `null`, but the array element or property remains in the object. With the `delete` operator, you can completely remove the element or property.

There is special behavior about deleting an array item that you should bear in mind. If your array uses numeric indices, a deletion of a given index removes that index value from the total array but without collapsing the array (which would alter index values of items higher than the deleted item). For example, consider the following simple dense array:

```
var oceans = new Array("Atlantic", "Pacific", "Indian","Arctic")
```

This kind of array automatically assigns numeric indices to its entries for addressing later in constructions, such as `for` loops:

```
for (var i = 0; i < oceans.length; i++) {
  if (oceans[i] == form.destination.value) {
    statements
  }
}
```

If you then issue the statement

```
delete oceans[2]
```

the array undergoes significant changes. First, the third element is removed from the array. Note that the length of the array does not change. Even so, the index

value (2) is removed from the array, such that schematically the array looks as the following:

```
oceans[0] = "Atlantic"
oceans[1] = "Pacific"
oceans[3] = "Arctic"
```

If you try to reference `oceans[2]` in this collection, the result is `undefined`.

The `delete` operator works best on arrays that have named indices. Your scripts will have more control over the remaining entries and their values, because they don't rely on what could be a missing entry of a numeric index sequence.

One aspect of this deletion action that JavaScript doesn't provide is absolute control over memory utilization. All garbage collection is managed by the JavaScript interpreter engine, which tries to recognize when items occupying memory are no longer needed, at which time the unused browser's application memory may be recovered. But you cannot force the browser to perform its garbage collection task.

in

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `in` operator lets a script statement inspect an object to see if it has a named property or method. The operand to the left of the operator is a string reference to the property or method (just the method name, without parentheses); the operand to the right of the operator is the object being inspected. If the object knows the property or method, the expression returns `true`. Thus, you can use the `in` operator in expressions used for conditional expressions.

You can experiment with this operator in The Evaluator. For example, to prove that the `write()` method is implemented for the `document` object, the expression you type into the top text box of The Evaluator is:

```
"write" in document
```

But compare the implementation of the W3C DOM `document.createAttribute()` method in IE5.5 and NN6:

```
"createAttribute" in document
```

In NN6, the result is `true`, while in IE5.5, the result is `false`.

Having this operator around for conditional expressions lets you go much beyond simple object detection for branching code. For example, if you intend to use `document.createAttribute()` in your script, you can make sure that the method is supported before invoking it (assuming your users all have browsers that know the `in` operator).

instanceof

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓				✓	✓

The `instanceof` operator (not implemented in IE5/Mac) lets a script test whether an object is an instance of a particular JavaScript native object or DOM object (in NN6). The operand to the left side of the operator is the value under test; the value to the right of the operand is a reference to the root class from which the value is suspected of being constructed.

For native JavaScript classes, the kinds of object references to the right of the operator include such static objects as `Date`, `String`, `Number`, `Boolean`, `Object`, `Array`, and `RegExp`. You sometimes need to be mindful of how native JavaScript classes can sometimes be children of other native classes, which means that a value may be an instance of two different static objects. For example, consider the following sequence (which you can follow along in The Evaluator):

```
a = new Array(1,2,3)
a instanceof Array
```

The second statement yields a result of `true`, because the `Array` constructor was used to generate the object. But the JavaScript `Array` is, itself, an instance of the root `Object` object. Therefore both of the following statements evaluate to `true`:

```
a instanceof Object
Array instanceof Object
```

NN6 also supports this functionality for W3C DOM objects to some degree. For instance, you can see that the `document` node is an instance of the root `Node` object:

```
document instanceof Node
```

But NN6 also erroneously reports instances of a variety of nodes and elements outside the strict inheritance hierarchy of the W3C DOM (for instance, NN6 also reports that `document` is an instance of `HTMLElement`, which it clearly is not).

new

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Most JavaScript core objects have constructor functions built into the language. To access those functions, you use the `new` operator along with the name of the constructor. The function returns a reference to the object instance, which your scripts can then use to get and set properties or invoke object methods. For example, creating a new date object requires invoking the `Date` object's constructor, as follows:

```
var today = new Date()
```

Some object constructor functions require parameters to help define the object. Others, as in the case of the `Date` object, can accept a number of different parameter formats, depending on the format of date information you have to set the initial object. The `new` operator can be used with the following core language objects:

JavaScript 1.0	JavaScript 1.1	JavaScript 1.2	JavaScript 1.5
Date	Array	RegExp	Error
Object	Boolean		
(Custom object)	Function		
	Number		
	String		

this

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

JavaScript includes an operator that allows script statements to refer to the very object in which they are located. The self-referential operator is `this`.

The most common application of the `this` operator is in event handlers that pass references of themselves to functions for further processing, as in

```
<INPUT TYPE="text" NAME="entry" onChange="process(this)">
```

A function receiving the value assigns it to a variable that can be used to reference the sender, its properties, and its methods.

Because the `this` operator references an object, that object's properties can be exposed with the aid of the operator. For example, to send the `value` property of a text input object to a function, the `this` operator stands in for the current object reference and appends the proper syntax to reference the `value` property:

```
<INPUT TYPE="text" NAME="entry" onChange="process(this.value)">
```

The `this` operator also works inside other objects, such as custom objects. When you define a constructor function for a custom object, using the `this` operator to define properties of the object and assign values to those properties is common practice. Consider the following example of an object creation sequence:

```
function bottledWater(brand, ozSize, flavor) {
    this.brand = brand
    this.ozSize = ozSize
    this.flavor = flavor
}
var myWater = new bottledWater("Crystal Springs", 16, "original")
```

When the new object is created via the constructor function, the `this` operators define each property of the object and then assign the corresponding incoming value to that property. Using the same names for the properties and parameter variables is perfectly fine and makes the constructor easy to maintain.

By extension, if you assign a function as an object's property (to behave as a method for the object), the `this` operator inside that function refers to the object invoking the function, offering an avenue to the object's properties. For example, if I

add the following function definition and statement to the `myWater` object created just above, the function can directly access the `brand` property of the object:

```
function adSlogan() {
    return "Drink " + this.brand + ", it's wet and wild!"
}
myWater.getSlogan = adSlogan
```

When a statement invokes the `myWater.getSlogan()` method, the object invokes the `adSlogan()` function, but all within the context of the `myWater` object. Thus, the `this` operator applies to the surrounding object, making the `brand` property available via the `this` operator (`this.brand`).

Miscellaneous Operators

The final group of operators doesn't fit into any of the previous categories, but they are no less important.

,

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

The comma operator indicates a series of expressions that are to be evaluated in left-to-right sequence. Most typically, this operator is used to permit multiple variable initializations. For example, you can combine the declaration of several variables in a single `var` statement, as follows:

```
var name, address, serialNumber
```

Another situation where you could use this operator is within the expressions of a `for` loop construction. In the following example, two different counting variables are initialized and incremented at different rates. When the loop begins, both variables are initialized at zero (they don't have to be, but this example starts that way); for each subsequent trip through the loop, one variable is incremented by one, while the other is incremented by 10:

```
for (var i=0, j=0; i < someLength; i++, j+10) {
    ...
}
```

Don't confuse the comma operator with the semi-colon delimiter between statements.

? :

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

The conditional operator is a shortcut way of expressing an `if . . . else` conditional construction covered in Chapter 39. This operator is typically used in concert with an assignment operator to assign one of two values to a variable based on the result of a condition expression. The formal syntax for the conditional operator is:

```
condition ? expressionIfTrue : expressionIfFalse
```

If used with an assignment operator, the syntax is:

```
var = condition ? expressionIfTrue : expressionIfFalse
```

No matter how you use the operator, the important point to remember is that an expression that contains this operator evaluates to one of the two expressions following the question mark symbol. In truth, either expression could invoke any JavaScript, including calling other functions or even nesting further conditional operators within one of the expressions to achieve the equivalent of nested `if . . . else` constructions. To assure proper resolution of nested conditionals, surround inner expressions with parentheses to make sure that they evaluate before the outer expression evaluates. As an example, the following statement assigns one of three strings to a variable depending on the date within a month:

```
var monthPart = (dateNum <= 10) ? "early" : ((dateNum <= 20) ? "middle" : "late")
```

When the statement is evaluated, the inner conditional expression at the right of the first colon is evaluated, returning either `middle` or `late`; then the outer conditional expression is evaluated, returning either `early` or the result of the inner conditional expression.

typeof

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓	✓	✓	✓	✓	✓

Unlike most other operators, which are predominantly concerned with arithmetic and logic, the unary `typeof` operator defines the kind of value to which a variable or expression evaluates. Typically, this operator is used to identify whether a variable value is one of the following types: number, string, boolean, object, function, or undefined.

Having this investigative capability in JavaScript is helpful because variables cannot only contain any one of those data types but can change their data type on the fly. Your scripts may need to handle a value differently based on the value's type. The most common use of the `typeof` property is as part of a condition. For example:

```
if (typeof myVal == "number") {
    myVal = parseInt(myVal)
}
```

The evaluated value of the `typeof` operation is, itself, a string.

void

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

In all scriptable browsers you can use the `javascript:` pseudo-protocol to supply the parameter for `HREF` and `SRC` attributes in HTML tags, such as links. In the process, you have to be careful that the function or statement being invoked by the URL does not return or evaluate to any values. If a value comes back from such an expression, then that value or sometimes the directory of the client’s hard disk often replaces the page content. To avoid this possibility use the `void` operator in front of the function or expression being invoked by the `javascript: URL`.

The best way to use this construction is to place the operator before the expression or function and separate them by a space, as in

```
javascript: void doSomething()
```

On occasion, you may have to wrap the expression inside parentheses after the `void` operator. Using parentheses is necessary only when the expression contains operators of a lower precedence than the `void` operator (see the following section, “Operator Precedence”). But don’t automatically wrap all expressions in parentheses, because some browsers can experience problems with these. Even so, it is common practice to assign the following URL to the `HREF` attribute of an `A` link whose `onClick` event handler does all of the work:

```
HREF="javascript: void (0)"
```

The `void` operator makes sure the function or expression returns no value that the HTML attribute can use. Such a link’s `onClick` event handler should also inhibit the natural behavior of a clicked link (for example, by evaluating to `return false`).

Operator Precedence

When you start working with complex expressions that hold a number of operators (for example, Listing 40-2), knowing the order in which JavaScript evaluates those expressions is vital. JavaScript assigns different priorities or weights to types of operators in an effort to achieve uniformity in the way it evaluates complex expressions.

In the following expression

```
10 + 4 * 5 // result = 30
```

JavaScript uses its precedence scheme to perform the multiplication before the addition — regardless of where the operators appear in the statement. In other words, JavaScript first multiplies 4 by 5, and then adds that result to 10 to get a result of 30. That may not be the way you want this expression to evaluate. Perhaps your intention was to add the 10 and 4 first and then to multiply that sum by 5. To make that happen, you have to override JavaScript’s natural operator precedence. To do that, you must use parentheses to enclose an operator with lower precedence.

The following statement shows how you adjust the previous expression to make it behave differently:

```
(10 + 4) * 5 // result = 70
```

That one set of parentheses has a great impact on the outcome. Parentheses have the highest precedence in JavaScript, and if you nest parentheses in an expression, the innermost set evaluates first.

For help in constructing complex expressions, refer to Table 40-10 for JavaScript's operator precedence. My general practice: When in doubt about complex precedence issues, I build the expression with lots of parentheses according to the way I want the internal expressions to evaluate.

Table 40-10: JavaScript Operator Precedence

<i>Precedence Level</i>	<i>Operator</i>	<i>Notes</i>
1	()	From innermost to outermost
	[]	Array index value
	function()	Any remote function call
2	!	Boolean Not
	~	Bitwise Not
	-	Negation
	++	Increment
	--	Decrement
	new	
	typeof	
	void	
	delete	Delete array or object entry
3	*	Multiplication
	/	Division
	%	Modulo
4	+	Addition
	-	Subtraction
5	<<	Bitwise shifts
	>	
	>>	
6	<	Comparison operators
	<=	

<i>Precedence Level</i>	<i>Operator</i>	<i>Notes</i>
	>	
	>=	
7	==	Equality
	!=	
8	&	Bitwise And
9	^	Bitwise XOR
10		Bitwise Or
11	&&	Boolean And
12		Boolean Or
13	?	Conditional expression
14	=	Assignment operators
	+=	
	-=	
	*=	
	/=	
	%=	
	<<=	
	>=	
	>>=	
	&=	
	^=	
	=	
15	,	Comma (parameter delimiter)

This precedence scheme is devised to help you avoid being faced with two operators from the same precedence level that often appear in the same expression. When it happens (such as with addition and subtraction), JavaScript begins evaluating the expression from left to right.

One related fact involves a string of Boolean expressions strung together for a condition statement (Listing 40-2). JavaScript follows what is called *short-circuit evaluation*. As the nested expressions are evaluated left to right, the fate of the entire condition can sometimes be determined before all expressions are evaluated. Any time JavaScript encounters an And operator, if the left operand evaluates to `false`, the entire expression evaluates to `false` without JavaScript's even bothering to evaluate the right operand. For an Or operator, if the left operand is `true`, JavaScript short-circuits that expression to `true`. This feature can trip you up if you don't perform enough testing on your scripts: If a syntax error or other error exists

in a right operand, and you fail to test the expression in a way that forces that right operand to evaluate, you may not know that a bug exists in your code. Users of your page, of course, will find the bug quickly. Do your testing to head bugs off at the pass.

Notice, too, that all math and string concatenation is performed prior to any comparison operators. This enables all expressions that act as operands for comparisons to evaluate fully before they are compared.

The key to working with complex expressions is to isolate individual expressions and to try them out by themselves, if you can. See additional debugging tips in Chapter 45.

41

CHAPTER

Functions and Custom Objects

By now, you've seen dozens of JavaScript functions in action and probably have a pretty good feel for the way they work. This chapter provides the function object specification and delves into the fun prospect of creating objects in your JavaScript code. (That includes objects that have properties and methods, just like the big boys.)

Function Object

<i>Properties</i>	<i>Methods</i>
arguments	apply()
arity	call()
caller	toString()
constructor	valueOf()
length	
prototype	

Syntax

Creating a function object:

```
function functionName([arg1,...[,argN]]) {  
    statement(s)  
}  
var funcName = new Function(["argName1",...[, "argNameN"],  
"statement1;...[,statementN]")  
object.eventHandlerName = function([arg1,...[,argN]])  
{statement(s)}
```

Accessing function object properties and methods:

```
functionObject.property | method([parameters])
```

In This Chapter

Creating function blocks

Passing parameters to functions

Creating your own objects

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	(✓)	✓	✓	✓	(✓)	✓	✓	✓	✓

About this object

JavaScript accommodates what other languages might call procedures, subroutines, and functions all in one type of structure: the *custom function*. A function may return a value (if programmed to do so with the `return` keyword), but it does not have to return any value. Except for JavaScript code that executes as the document loads, all deferred processing takes place in functions.

While you can create functions that are hundreds of lines long, I recommend you break up longer processes into shorter functions. Among the reasons for doing so: smaller chunks are easier to write and debug; building blocks make it easier to visualize the entire script; you can make functions generalizable and reusable for other scripts; and other parts of the script or other open frames can use the functions.

Learning how to write good, reusable functions takes time and experience. But the earlier you understand the importance of this concept, the more you will be on the lookout for good examples in other people's scripts on the Web.

Creating functions

The standard way of defining a function in your script means following a simple pattern and then filling in the details. The formal syntax definition for a function is:

```
function functionName( [arg1] ... [, argN] ) {
    statement(s)
}
```

The task of assigning a function name helps you determine the precise scope of activity of the function. If you find that you can't reduce the planned task for the function to a simple one- to three-word name (which is then condensed into one contiguous sequence of characters for the `functionName`), perhaps you're asking the function to do too much. A better idea may be to break the job into two or more functions. As you start to design a function, be on the lookout for functions that you can call from the one you're writing. If you find yourself copying and pasting lines of code from one part of a function to another because you're performing the same operation in different spots within the function, it may be time to break that segment out into its own function.

Starting with Navigator 3 (and Internet Explorer 3 with JScript.dll version2), you can also create what is called an *anonymous function* using the new `Function()` constructor. In reality, you assign a name to this "anonymous" function as follows:

```
var funcName = new Function(["argName1",...[, "argNameN"],
"statement1;...[,statementN]"])
```

This other way of building a function is particularly helpful when your scripts need to create a function after a document loads. All the components of a function are present in this definition. Each function parameter name is supplied as a string value, separated from each other by commas. The final parameter string consists of

the statements that execute whenever the function is called. Separate each JavaScript statement with a semicolon, and enclose the entire sequence of statements inside quotes, as in the following:

```
var willItFit = new Function("width","height",
"var sx = screen.availWidth; var sy = screen.availHeight; return (sx >= width &&
sy >= height)");
```

The `willItFit()` function takes two parameters; the body of the function defines two local variables (`sx` and `sy`) and then returns a Boolean value of `true` if the incoming parameters are smaller than the local variables. In traditional form, this function is defined as follows:

```
function willItFit(width, height) {
    var sx = screen.availWidth
    var sy = screen.availHeight
    return (sx >= width && sy >= height)
}
```

Once this function exists in the browser's memory, you can invoke it like any other function:

```
if (willItFit(400,500)) {
    statements to load image
}
```

One last function creation format is available in NN4+. This advanced technique, called a *lambda expression*, provides a shortcut for creating a reference to an anonymous function (truly anonymous because the function has no name that you can reference later). The common application of this technique is to assign function references to event handlers when the NN event object also must be passed. The following is an example of how to assign an anonymous function to an `onChange` event handler for a form control:

```
document.forms[0].age.onChange = function(event)
{isNumber(document.forms[0].age)}
```

Nesting functions

NN4+ and IE4+ also provide for nesting functions inside one another. In all prior scripting, each function definition is defined at the global level whereby every function is exposed and available to all other scripting. With nested functions, you can encapsulate the exposure of a function inside another and make that nested function private to the enclosing function. Of course I don't recommend reusing names in this fashion, but you can create nested functions with the same name inside multiple global level functions, as the following skeletal structure shows:

```
function outerA() {
    statements
    function innerA() {
        statements
    }
    statements
}
```

```
function outerB() {
  statements
  function innerA() {
    statements
  }
  function innerB() {
    statements
  }
  statements
}
```

A good time to apply a nested function is when a sequence of statements need to be invoked in multiple places within a large function but those statements have meaning only within the context of the larger function. In other words, rather than break out the repeated sequence as a separate global function, you keep it all within the scope of the larger function.

You can access a nested function only from statements in its containing function (and in any order). Moreover, all variables defined in the outer function (including parameter variables) are accessible to the inner function; but variables defined in an inner function are not accessible to the outer function. See the section, “Variable Scope: Globals and Locals” later in this chapter for details on how variables are visible to various components of a script.

Function parameters

The function definition requires a set of parentheses after the `functionName`. If the function does not rely on any information arriving with it when invoked, the parentheses can be empty. But when some kind of data is arriving with a call to the function, you need to assign names to each parameter. Virtually any kind of value can be a parameter: strings, numbers, Booleans, and even complete object references such as a form or form element. Choose names for these variables that help you remember the content of those values; also, avoid reusing existing object names as variable names because it's easy to get confused when objects and variables with the same name appear in the same statements. You must avoid using JavaScript keywords (including the reserved words listed in Appendix B) and any global variable name defined elsewhere in your script. (See more about global variables in the following sections.)

JavaScript is forgiving about matching the number of parameters in the function definition with the number of parameters passed along from the calling statement. If you define a function with three parameters and the calling statement specifies only two, the third parameter variable value in that function is assigned a `null` value. For example:

```
function oneFunction(a, b, c) {
  statements
}
oneFunction("George", "Gracie")
```

In the preceding example, the values of `a` and `b` inside the function are "George" and "Gracie", respectively; the value of `c` is `null`.

At the opposite end of the spectrum, JavaScript also doesn't balk if you send more parameters from the calling statement than the number of parameter variables specified in the function definition. In fact, the language includes a mechanism—the `arguments` property—that you can add to your function to gather any extraneous parameters that should read your function.

Properties

`arguments`

Value: Array of arguments

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

When a function receives parameter values from the statement that invokes the function, those parameter values are silently assigned to the `arguments` property of the function object. This property is an array of the values, with each parameter value assigned to a zero-based index entry in the array—whether or not parameters are defined for it. You can find out how many parameters are sent by extracting `functionName.arguments.length`. For example, if four parameters are passed, `functionName.arguments.length` returns 4. Then, you can use array notation (`functionName.arguments[i]`) to extract the values of any parameter(s) you want.

Theoretically, you never have to define parameter variables for your functions by extracting the desired arguments array entry instead. Well-chosen parameter variable names, however, are much more readable, so I recommend them over the `arguments` property in most cases. But you may run into situations in which a single function definition needs to handle multiple calls to the function when each call may have a different number of parameters. The function knows how to handle any arguments over and above the ones given names as parameter variables.

See Listings 41-1 and 41-2 for a demonstration of both the `arguments` and `caller` properties.

`arity`

Value: Integer

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					

See the discussion of the `length` property later in this chapter.

caller

Value: Function Object Reference

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓			✓	✓	✓	✓

Note

The `caller` property, not part of the ECMA-262 standard, was removed from NN for version 6.

When one function invokes another, a chain is established between the two primarily so that a returned value knows where to go. Therefore, a function invoked by another maintains a reference to the function that called it. Such information is automatically stored in a function object as the `caller` property. This relationship reminds me a bit of a subwindow's `opener` property, which points to the window or frame responsible for the subwindow's creation. The value is valid only while the called function is running at the request of another function; when a function isn't running, its `caller` property is `null`.

The value of the `caller` property is a reference to a function object, so you can inspect its arguments and `caller` properties (in case it was called by yet another function). Thus, a function can look back at a calling function to see what values it was passed.

The `functionName.caller` property reveals the contents of an entire function definition if the current function was called from another function (including an event handler). If the call for a function comes from a regular JavaScript statement not originating from inside a function, the `functionName.caller` property is `null`.

To help you grasp all that these two properties yield, study Listing 41-1.

Listing 41-1: A Function's arguments and caller Properties

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function hansel(x,y) {
    var args = hansel.arguments
    document.write("<P>hansel.caller is " + hansel.caller + "<BR>")
    document.write("hansel.arguments.length is " + hansel.arguments.length +
"<BR>")
    for (var i = 0; i < args.length; i++) {
        document.write("argument " + i + " is " + args[i] + "<BR>")
    }
    document.write("</P>")
}
}
```

```

function gretel(x,y,z) {
    today = new Date()
    thisYear = today.getFullYear()
    hansel(x,y,z,thisYear)
}
</SCRIPT>
</HEAD>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
hansel(1, "two", 3);
gretel(4, "five", 6, "seven");
</SCRIPT>
</BODY>
</HTML>

```

When you load this page, the following results appear in the browser window (although the caller property values show undefined for NN6):

```

hansel.caller is null
hansel.arguments.length is 3
argument 0 is 1
argument 1 is two
argument 2 is 3

```

```

hansel.caller is function gretel(x, y, z) { today = new Date(); thisYear =
today.getFullYear(); hansel(x, y, z, thisYear); }

```

```

hansel.arguments.length is 4
argument 0 is 4
argument 1 is five
argument 2 is 6
argument 3 is 2001 (or whatever the current year is)

```

As the document loads, the `hansel()` function is called directly in the body script. It passes three arguments, even though the `hansel()` function defines only two. The `hansel.arguments` property picks up all three arguments just the same. The main body script then invokes the `gretel()` function, which, in turn, calls `hansel()` again. But when `gretel()` makes the call, it passes four parameters. The `gretel()` function picks up only three of the four arguments sent by the calling statement. It also inserts another value from its own calculations as an extra parameter to be sent to `hansel()`. The `hansel.caller` property reveals the entire content of the `gretel()` function, whereas `hansel.arguments` picks up all four parameters, including the year value introduced by the `gretel()` function.

Neither the `caller` nor `arguments` properties of a function object appear in the ECMA-262 Edition 3 specification. While NN6 dropped the `caller` property, it continues to support the `arguments` property probably because a lot of scripters use it.

constructor

See `string.constructor` (Chapter 34).

length

Value: Integer

Read-Only

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓		✓	✓	✓	✓

As the `arguments` property of a function proves, JavaScript is very forgiving about matching the number of parameters passed to a function with the number of parameter variables defined for the function. But a script can examine the `length` property of a function object to see precisely how many parameter variables are defined for a function. A reference to the property starts with the function name representing the object. For example, consider the following function definition shell:

```
function identify(name, rank, serialNum) {
    ...
}
```

A script statement anywhere outside of the function can read the number of parameters with the reference:
`identify.length`

The value of the property in the preceding example is 3. The `length` property supercedes the NN-only `arity` property.

prototype

See `Array.prototype` (Chapter 37).

Methods

`apply([thisObj[, argumentsArray]])`
`call([thisObj[, arg1[, arg2[, ...argN]]]])`

Returns: Nothing.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `apply()` and `call()` methods of a function object invoke the function. This may seem redundant to the normal way in which script statements invoke functions by simply naming the function, following it with parentheses, passing parameters, and so on. The difference with these methods is that you can invoke the

function if your script has only a reference to the function. For example, if your script defines a function via the new `Function()` constructor (or other anonymous shortcut supported by the browser), you receive a reference to the function as a result of the constructor. To invoke the function later using only that reference (presumably preserved in a global variable), use either the `apply()` or `call()` method. Both of these methods achieve the same result, but choosing one method over the other depends on the form in which the function's parameters are conveyed (more about that in a moment).

The first parameter of both methods is a reference to the object that the function treats as the current object. For garden-variety functions defined in your script, use the keyword `this`, which means that the function's context becomes the current object (just like a regular function). In fact, if there are no parameters to be sent to the function, you can omit parameters to both methods altogether.

The object reference comes into play when the function being invoked is one that is normally defined as a method to a custom object. (I cover some of these concepts later in this chapter, so you may need to return here after you are familiar with custom objects.) Consider the following code that generates a custom object and assigns a method to the object to display an alert about properties of the object:

```
// function to be invoked as a method from a 'car' object
function showCar() {
    alert(this.make + " : " + this.color)
}
// 'car' object constructor function
function car(make, color) {
    this.make = make
    this.color = color
    this.show = showCar
}
// create instance of a 'car' object
var myCar = new car("Ford", "blue")
```

The normal way of getting the `myCar` object to display an alert about its properties is:

```
myCar.show()
```

At that point, the `showCar()` function runs, picking up the current `car` object as the context for the `this` references in the function. In other words, when the `showCar()` function runs as a method of the object, the function treats the object as the “current object.”

With the `call()` or `apply()` methods, however, you don't have to bind the `showCar()` function to the `myCar` object. You can omit the statement in the `car()` constructor that assigns the `showCar` function to a method name for the object. Instead, a script can invoke the `showCar()` method and instruct it to treat `myCar` as the current object:

```
showCar.call(myCar)
```

The `showCar()` function operates just as before, and the object reference in the `call()` method's first parameter slot is treated as the current object for the `showCar()` function.

As for succeeding parameters, the `apply()` method's second parameter is an array of values to be passed as parameters to the current function. The order of the values must match the order of parameter variables defined for the function. The `call()` method, on the other hand, enables you to pass individual parameters in a comma-delimited list. Your choice depends on how the parameters are carried along in your script. If they're already in array form, then use the `apply()` method; otherwise, use the `call()` method. The (ECMA) recommended way to invoke a function through this mechanism when no parameters need to be passed is via the `call()` method.

`toString()` `valueOf()`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

Scripts rarely, if ever, summon the `toString()` and `valueOf()` methods of a function object. They work internally to allow debugging scripts to display a string version of the function definition. For example, when you enter the name of a function defined in The Evaluator into the top text box, JavaScript automatically converts the function to a string so that its “value” can be displayed in the Results box. Using these methods or parsing the text they return has little, if any, practical application.

Function Application Notes

Understanding the ins and outs of JavaScript functions is the key to successful scripting, especially for complex applications. Additional topics covered in this chapter include the ways to invoke functions, variable scope in and around functions, recursion, and the design of reusable functions.

Invoking Functions

A function doesn't perform any work until a script calls it by name or reference. Scripts invoke functions (that is, get functions to do something) via four routes: document object event handlers; JavaScript statements; `HREF` attributes pointing to a `javascript: URL`; and the more recent `call()` and `apply()` methods of function objects. The one approach not discussed at length yet in this book is the `javascript: URL` (some say pseudo-URL).

Several HTML tags have `HREF` attributes that normally point to Internet URLs for navigating to another page or loading a MIME file that requires a helper application or plug-in. These HTML tags are usually tags for clickable objects, such as links and client-side image map areas.

A JavaScript-enabled browser has a special, built-in URL pseudo-protocol—`javascript:`—that lets the `HREF` attribute point to a JavaScript function or method rather than to a URL out on the Net. For example, it is common practice to use the `javascript:` URL to change the contents of two frames from a single link. Because the `HREF` attribute is designed to point to only a single URL, you'd be out of luck without a convenient way to put multiframe navigation into your hands. Implement multiframe navigation by writing a function that sets the `location.href` properties of the two frames; then invoke that function from the `HREF` attribute. The following example shows what the script may look like:

```
function loadPages() {
    parent.frames[1].location.href = "page2.html"
    parent.frames[2].location.href = "instrux2.html"
}
...
<A HREF="javascript:loadPages()">Next</A>
```

**Note**

These kinds of function invocations can include parameters, and the functions can do anything you want. One potential side effect to watch out for occurs when the function returns a value (perhaps the function is also invoked from other script locations where a returned value is expected). Because the `HREF` attribute sets the `TARGET` window to whatever the attribute evaluates to, the returned value is assigned to the `TARGET` window—probably not what you want.

To prevent the assignment of a returned value to the `HREF` attribute, prefix the function call with the `void` operator:

```
<A HREF="javascript:void loadPages()">
```

If you don't want the `HREF` attribute to do anything (that is, let the `onClick` event handler do all the work), then assign a blank function after the operator:

```
<A HREF="javascript:void (0)">
```

Experienced programmers of many other languages recognize this operator as a way of indicating that no values are returned from a function or procedure. The operator has that precise functionality here, but in a nontraditional location.

Variable Scope: Globals and Locals

A variable can have two scopes in JavaScript. As you might expect, any variable initialized within the main flow of a script (not inside a function) is a *global variable* in that any statement in the same document's script can access it by name. You can, however, also initialize variables inside a function (in a `var` statement) so the variable name applies only to statements inside that function. By limiting the scope of the variable to a single function, you can reuse the same variable name in multiple functions thereby enabling the variables to carry very different information in each function. Listing 41-2 demonstrates the various possibilities.

Listing 41-2: Variable Scope Workbench Page

```
<HTML>
<HEAD>
<TITLE>Variable Scope Trials</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var headGlobal = "Gumby"
function doNothing() {
    var headLocal = "Pokey"
    return headLocal
}
</SCRIPT>
</HEAD>

<BODY>
<SCRIPT LANGUAGE="JavaScript">
// two global variables
var aBoy = "Charlie Brown"
var hisDog = "Snoopy"
function testValues() {
    var hisDog = "Gromit" // initializes local version of "hisDog"
    var page = ""
    page += "headGlobal is: " + headGlobal + "<BR>"
    // page += "headLocal is: " + headLocal + "<BR>" // headLocal not defined
    page += "headLocal value returned from head function is: " + doNothing() +
"<P>"
    page += " aBoy is: " + aBoy + "<BR>" // picks up global
    page += "local version of hisDog is: " + hisDog + "<P>" // "sees" only local
    document.write(page)
}
testValues()
document.write("global version of hisDog is intact: " + hisDog)
</SCRIPT>
</BODY>
</HTML>
```

In this page, you define a number of variables — some global, others local — that are spread out in the document's Head and Body sections. When you load this page, it runs the `testValues()` function, which accounts for the current values of all the variable names. The script then follows up with one more value extraction that was masked in the function. The results of the page look like this:

```
headGlobal is: Gumby
headLocal value returned from head function is: Pokey
```

```
aBoy is: Charlie Brown
local version of hisDog is: Gromit
```

```
global version of hisDog is intact: Snoopy
```

Examine the variable initialization throughout this script. In the Head, you define the first variable (`headGlobal`) as a global style outside of any function definition. The `var` keyword for the global variable is optional but often helpful for enabling you to see at a glance where you initialize your variables. You then create a short function, which defines a variable (`headLocal`) that only statements in the function can use.

In the Body, you define two more global variables: `aBoy` and `hisDog`. Inside the Body's function (for purposes of demonstration), you reuse the `hisDog` variable name. By initializing `hisDog` with the `var` statement inside the function, you tell JavaScript to create a separate variable whose scope is only within the function. This initialization does not disturb the global variable of the same name. It can, however, make things confusing for you as the script author.

Statements in this script attempt to collect the values of variables scattered around the script. Even from within this script, JavaScript has no problem extracting global variables directly—including the one defined in the Head. But JavaScript cannot get the local variable defined in the other function—that `headLocal` variable is private to its own function. Trying to run a script that references that variable value will result in an error message saying that the variable name is not defined. In the eyes of everyone else outside of the `doNothing()` function, that's true. If you really need that value, you can have the function return the value to a calling statement as you do in the `testValues()` function.

Near the end of the function, the script reads the `aBoy` global value without a hitch. But because you initialized a separate version of `hisDog` inside that function, only the localized version is available to the function. If you reassign a global variable name inside a function, you cannot access the global version from inside that function.

As proof that the global variable—whose name was reused inside the `testValues()` function—remains untouched, the script writes that value to the end of the page for all to see. Charlie Brown and his dog are reunited.

A benefit of this variable-scoping scheme is that you can reuse “throw-away” variable names in any function you like. For instance, you can use the `i` loop counting variable in every function that employs loops. (In fact, you can reuse it in multiple `for` loops of the same function because the `for` loop reinitializes the value at the start of the loop.) If you pass parameters to a function, you can assign to those parameter variables the same names to aid in consistency. For example, a common practice is to pass an entire form object reference as a parameter to a function (using a `this.form` parameter in the event handler). For every function that catches one of these objects, you can use the variable name `form` in the parameter:

```
function doSomething(form) {  
    statements  
}  
...  
<INPUT TYPE="button" VALUE="Do Something" onClick="doSomething(this.form)">
```

If five buttons on your page pass their form objects as parameters to five different functions, each function can assign `form` (or whatever you want to use) to that parameter value.

I recommend reusing variable names only for these “throwaway” variables. In this case, the variables are all local to functions, so the possibility of a mix-up with global variables does not exist. But the thought of reusing a global variable name as, say, a special case inside a function sends shivers up my spine. Such a tactic is doomed to cause confusion and error.

Some programmers devise naming conventions to avoid reusing global variables as local variables. A popular scheme puts a lowercase “g” in front of any global variable name. In the example from Listing 41-2, you can name the global variables

```
gHeadGlobal  
gABoy  
gHisDog
```

Then, if you define local variables, don’t use the leading “g.” Any scheme you employ to prevent the reuse of variable names in different scopes is fine as long as it does the job.

In a multiframe or multiwindow environment, your scripts can also access global variables from any other document currently loaded into the browser. For details about this level of access, see Chapter 16.

Variable scoping rules apply equally to nested functions in NN4+ and IE4+. Any variables defined in an outer function (including parameter variables) are exposed to all functions nested inside. But if you define a new local variable inside a nested function, that variable is not available to the outer function. Instead, you can return a value from the nested function to the statement in the outer function that invokes the nested function.

Parameter variables

When a function receives data in the form of parameters, remember that the values may be copies of the data (in the case of run-of-the-mill data values) or references to real objects (such as a form object). In the latter case, you can change the object’s modifiable properties in the function when the function receives the object as a parameter, as shown in the following example:

```
function validateCountry (form) {  
    if (form.country.value == "") {  
        form.country.value = "USA"  
    }  
}
```

Therefore, whenever you pass an object reference as a function parameter, be aware that the changes you make to that object in its “passed” form affect the real object.

As a matter of style, if my function needs to extract properties or results of methods from passed data (such as object properties or string substrings), I like to do that at the start of the function. I initialize as many variables as needed for each piece of data used later in the function. This task enables me to assign meaningful names to the data chunks, rather than rely on potentially long references within the working part of the function (such as using a variable like `inputStr` instead of `form.entry.value`).

Recursion in functions

Functions can call themselves — a process known as *recursion*. The classic example of programmed recursion is the calculation of the factorial (the factorial for a value of 4 is $4 * 3 * 2 * 1$), shown in Listing 41-3 (not on the CD-ROM).

In the third line of this function, the statement calls itself, passing along a parameter of the next lower value of n . As this function executes, diving ever deeper into itself, JavaScript watches intermediate values and performs the final evaluations of the nested expressions. Be sure to test any recursive function carefully. In particular, make sure that the recursion is finite: that a limit exists for the number of times it can recurse. In the case of Listing 41-3, that limit is the initial value of n . Failure to watch out for this limit may cause the recursion to overpower the limits of the browser's memory and even lead to a crash.

Listing 41-3: A JavaScript Function Utilizing Recursion

```
function factorial(n) {
    if (n > 0) {
        return n * (factorial(n-1))
    } else {
        return 1
    }
}
```

Turning functions into libraries

As you start writing functions for your scripts, be on the lookout for ways to make functions generalizable (written so that you can reuse the function in other instances, regardless of the object structure of the page). The likeliest candidates for this kind of treatment are functions that perform specific kinds of validation checks (see examples in Chapter 43), data conversions, or iterative math problems.

To make a function generalizable, don't let it make any references to specific objects by name. Object names generally change from document to document. Instead, write the function so that it accepts a named object as a parameter. For example, if you write a function that accepts a `text` object as its parameter, the function can extract the object's data or invoke its methods without knowing anything about its enclosing form or name. Look again, for example, at the `factorial()` function in Listing 41-4 — but now as part of an entire document.

Listing 41-4: Calling a Generalizable Function

```
<HTML>
<HEAD>
<TITLE>Variable Scope Trials</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

Continued

Listing 41-4 (continued)

```
function factorial(n) {
    if (n > 0) {
        return n * (factorial(n - 1))
    } else {
        return 1
    }
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
Enter an input value: <INPUT TYPE="text" NAME="input" VALUE=0>
<P><INPUT TYPE="button" VALUE="Calc Factorial"
    onClick="this.form.output.value = factorial(this.form.input.value)">
<P>Results: <INPUT TYPE="text" NAME="output">
</FORM>
</BODY>
</HTML>
```

This function is designed to be generalizable, accepting only the input value (*n*) as a parameter. In the form, the `onClick` event handler of the button sends only the input value from one of the form's fields to the `factorial()` function. The returned value is assigned to the output field of the form. The `factorial()` function is totally ignorant about forms, fields, or buttons in this document. If I need this function in another script, I can copy and paste it into that script knowing that it has been pretested. Any generalizable function is part of my personal library of scripts—from which I can borrow—and saves me time in future scripting tasks.

You cannot always generalize a function. Somewhere along the line in your scripts, you must have references to JavaScript or custom objects. But if you find that you're frequently writing functions that perform the same kind of actions, see how you can generalize the code and put the results in your library of ready-made functions. And if your audience uses browsers from Navigator 3 onward (and later versions of Internet Explorer 3 onward), consider placing these library functions in an external `.js` library file. See Chapter 13 for details on this convenient way to share utility functions among many documents.

Custom Objects

In all the previous chapters of this book, you've seen how conveniently the browser document object models organize all the information about the browser window and its document. What may not be obvious from the scripting you've done so far is that JavaScript enables you to create your own objects in memory—objects with properties and methods. These objects are not user-interface elements on the page but rather the kinds of objects that may contain data and script functions (behaving as methods) whose results the user can see displayed in the browser window.

You actually had a preview of this power in Chapter 37's discussion about arrays. An array, you recall, is an ordered collection of data. You can create a JavaScript array in which entries are labeled just like properties that you access via the now-familiar dot syntax (`arrayName[index].propertyName`). An object typically contains different kinds of data. It doesn't have to be an ordered collection of data—although your scripts can use objects in constructions that strongly resemble arrays. Moreover, you can attach any number of custom functions as methods for that object. You are in total control of the object's structure, data, and behavior.

An example – planetary objects

Building on your familiarity with the planetary data array created in Chapter 37, this chapter shows you how convenient it is to use the data when it is constructed in the form of custom objects. The application goal for the extended example in this section is to present a pop-up list of the nine planets of the solar system and display data about the selected planet. From a user-interface perspective (and for more exposure to multiframe environments), the resulting data displays in a separate frame of a two-frame window. This means your object method builds HTML on the fly and plugs it into the display frame. If you implement this application strictly for IE4+ and NN6, you can apply the same data to reconstruct the displayed table data for each user selection. The example as shown, however, is fully backward-compatible for all scriptable browsers.

In this chapter, instead of building arrays to hold the data, you build objects—one object for each planet. The design of your object has five properties and one method. The properties of each planet are: name, diameter, distance from the sun, year length, and day length. To assign more intelligence to these objects, you give each of them the capability to display their data in the lower frame of the window. You can conveniently define one function that knows how to behave with any of these planet objects, rather than having to define nine separate functions.

Listing 41-5 shows the source code for the document that creates the frameset for your planetary explorations; Listing 41-6 shows the entire HTML page for the object-oriented planet document, which appears in the top frame.

Listing 41-5: Framesetting Document for a Two-Frame Window

```
<HTML>
<HEAD>
<TITLE>Solar System Viewer</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function blank() {
    return "<HTML><BODY></BODY></HTML>"
}
</SCRIPT>
</HEAD>
<FRAMESET ROWS="50%,50%"
onLoad="Frame1.doDisplay(Frame1.document.forms[0].planetsList)">
    <FRAME NAME="Frame1" SRC="1st41-06.htm">
    <FRAME NAME="Frame2" SRC="javascript:parent.blank()">
</FRAMESET>
</HTML>
```

One item to point out in Listing 41-5 is that because the lower frame isn't filled until the upper frame's document loads, you need to assign some kind of URL for the SRC attribute of the second frame. Rather than add the extra transaction and file burden of a blank HTML document, here you use the `javascript: URL` to invoke a function. In this instance, I want the value returned from the function (a blank HTML page) to be reflected into the target frame (no `void` operator here). This method provides the most efficient way of creating a blank frame in a frameset.

Listing 41-6: Object-Oriented Planetary Data Presentation

```
<HTML>
<HEAD>
<TITLE>Our Solar System</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!-- start script
// method definition
function showPlanet() {
    var result = "<HTML><BODY><CENTER><TABLE BORDER=2>"
    result += "<CAPTION ALIGN=TOP>Planetary data for: <B>" + this.name +
"</B></CAPTION>"
    result += "<TR><TD ALIGN=RIGHT>Diameter:</TD><TD>" + this.diameter +
"</TD></TR>"
    result += "<TR><TD ALIGN=RIGHT>Distance from Sun:</TD><TD>" + this.distance +
"</TD></TR>"

```

The first task in the Head is to define the function that becomes a method in each of the objects. You must do this task before scripting any other code that adopts the function as its method. Failure to define the function ahead of time results in an error — the function name is not defined. If you compare the data extraction methodology with the function in the array version, notice that the parameter for the index value is gone and the reference to each property begins with *this*. Later, I return to the custom method after giving you a look at the rest of the Head code.

Next comes the object constructor function, which performs several important tasks. For one, everything in this function establishes the structure of your custom object: the properties available for data storage and retrieval and any methods that the object can invoke. The name of the function is the name you use later to create new instances of the object. Therefore, choosing a name that truly reflects the nature of the object is important. And, because you probably want to stuff some data into the function's properties to get one or more instances of the object loaded and ready for the page's user, the function definition includes parameters for each of the properties defined in this object definition.

Inside the function, you use the `this` keyword to assign data that comes in as parameters to labeled properties. For this example, I use the same names for both the incoming parameter variables and the properties. That's primarily for convenience (and is very common practice), but you can assign any variable and property names you want and connect them any way you like. In the `planet()` constructor function, five property slots are reserved for every instance of the object whether or not any data actually is placed in every property (any unassigned slot has a value of `null`).

The last entry in the `planet()` constructor function is a reference to the `showPlanet()` function defined earlier. Notice that the assignment statement doesn't refer to the function with its parentheses — just to the function name. When JavaScript sees this assignment statement, it looks back through existing definitions (those functions defined ahead of the current location in the script) for a match. If it finds a function (as it does here), JavaScript knows to assign the function to the identifier on the left side of the assignment statement. In doing this task with a function, JavaScript automatically sets up the identifier as a method name for this object. As you do in every JavaScript method you encounter, you must invoke a method by using a reference to the object, a period, and the method name followed by a set of parentheses. You see that syntax in a minute.

The next long block of statements creates the individual objects according to the definition established in the `planet()` constructor. Similar to an array, an assignment statement and the keyword `new` create an object. I assign names that are not only the real names of planets (the `Mercury` object name is the `Mercury planet` object) but that also can come in handy later when the `doDisplay()` function extracts names from the pop-up list in search of a particular object's data.

The act of creating a new object sets aside space in memory (associated with the current document) for this object and its properties. In this script, you create nine object spaces, each with a different set of properties. Notice that no parameter is sent (or expected at the function) that corresponds to the `showPlanet()` method. Omitting that parameter here is fine because the specification of that method in the object definition means that the script automatically attaches the method to every version (instance) of the `planet` object that it creates.

The last function definition, `doDisplay()`, is invoked whenever the user makes a choice from the list of planets in the upper frame. This function is also invoked via the frameset's `onLoad` event handler so that an initial table is displayed from the default selected item (see Figure 41-1). Invoking the function from the upper frame's `onLoad` event handler can cause problems (such as the failure of the other frame) if the frameset is not completely loaded.

Figure 41-1: An external and internal face-lift for an earlier application

The `onChange` event handler in the `SELECT` list passes that `SELECT` element's reference to the `doDisplay()` function. In that function, the `SELECT` object is assigned to a variable called `popup` to help you visualize that the object is the pop-up list. The first statement extracts the index value of the selected item. Using that index value, the script extracts the text. But things get a little tricky because you need to use that text string as a variable name—the name of the planet—and append it to the call to the `showPlanet()` method. To make the disparate data types come together, use the `eval()` function. Inside the parentheses, extract the string for the planet name and concatenate a string that completes the reference to the object's `showPlanet()` method. The `eval()` function evaluates that string, which turns it into a valid method call. Therefore, if the user selects Jupiter from the pop-up list, the method call becomes `Jupiter.showPlanet()`.

Now it's time to look back to the `showPlanet()` function/method definition at the top of the script. When that method runs in response to a user selection of the planet Jupiter, the method's only scope is of the Jupiter object. Therefore, all references to `this.propertyName` in `showPlanet()` refer to Jupiter only. The only possibility for `this.name` in the Jupiter object is the value assigned to the `name` property for Jupiter. The same goes for the rest of the properties extracted in the function/method.

Creating an array of objects

In Listing 41-6, each of the planet objects is assigned to a global variable whose name is that of the planet. If the idea of custom objects is new to you, this idea probably doesn't sound so bad because it's easy to visualize each variable representing an object. But, as shown in the `doDisplay()` function, accessing an object by name requires use of the `eval()` function to convert a string representation to a valid object reference. While it's not too important in this simple example, the `eval()` function is not particularly efficient in JavaScript. If you find yourself using

an `eval()` function, look for ways to improve efficiency such that you can reference an object by string. The way to accomplish that streamlining for this application is to place the objects in an array whose index values are the planet names.

To assign the custom objects in Listing 41-6 to an array, first create an empty array and then assign the result of each object constructor call to an entry in the array. The modified code section looks like the following (formatted to fit this printed page):

```
// create array
var planets = new Array()
// populate array with new planet objects
planets["Mercury"] =
    new planet("Mercury", "3100 miles", "36 million miles",
        "88 days", "59 days")
planets["Venus"] =
    new planet("Venus", "7700 miles", "67 million miles",
        "225 days", "244 days")
planets["Earth"] =
    new planet("Earth", "7920 miles", "93 million miles",
        "365.25 days", "24 hours")
planets["Mars"] =
    new planet("Mars", "4200 miles", "141 million miles",
        "687 days", "24 hours, 24 minutes")
planets["Jupiter"] =
    new planet("Jupiter", "88,640 miles", "483 million miles",
        "11.9 years", "9 hours, 50 minutes")
planets["Saturn"] =
    new planet("Saturn", "74,500 miles", "886 million miles",
        "29.5 years", "10 hours, 39 minutes")
planets["Uranus"] =
    new planet("Uranus", "32,000 miles", "1.782 billion miles",
        "84 years", "23 hours")
planets["Neptune"] =
    new planet("Neptune", "31,000 miles", "2.793 billion miles",
        "165 years", "15 hours, 48 minutes")
planets["Pluto"] =
    new planet("Pluto", "1500 miles", "3.67 billion miles",
        "248 years", "6 days, 7 hours")
```

The supreme advantage to this approach comes in a modified `doDisplay()` function, which can use the string value from the `SELECT` element directly without any conversion to an object reference:

```
// called from push button to invoke planet object method
function doDisplay(popup) {
    i = popup.selectedIndex
    planets[popup.options[i].text].showPlanet()
}
```

The presence of so many similar objects cries out for their storage as an array. Because the names play a key role in their choice for this application, the named index values work best; in other situations, you may prefer to use numeric indexes to facilitate looping through the array.

Adding a custom method

You're approaching advanced subject matter at this point, so I merely mention and briefly demonstrate an additional power of defining and using custom objects. A custom object can have a reference to another custom object as a property. Let's extend the planet example to help you understand the implications.

Say that you want to beef up the planet page with a photo of each planet. Each photo has a URL for the photo file; each photo also contains other information, such as the copyright notice and a reference number, which displays on the page for the user. One way to handle this additional information is to create a separate object definition for a photo database. Such a definition may look like this:

```
function photo(name, URL, copyright, refNum) {
    this.name = name
    this.URL = URL
    this.copyright = copyright
    this.refNum = refNum
}
```

You then need to create individual photo objects for each picture. One such definition may look like this:

```
mercuryPhoto = new photo("Planet Mercury", "/images/merc44.gif", "(c)1990 NASA",
28372)
```

Attaching a photo object to a planet object requires modifying the planet constructor function to accommodate one more property. The new planet constructor looks like this:

```
function planet(name, diameter, distance, year, day, photo) {
    this.name = name
    this.diameter = diameter
    this.distance = distance
    this.year = year
    this.day = day
    this.showPlanet = showPlanet
    this.photo = photo // add photo property
}
```

Once the photo objects are created, you can then create each planet object by passing one more parameter — a photo object you want associated with that object:

```
// create new planet objects, and store in a series of variables
Mercury = new planet("Mercury","3100 miles", "36 million miles", "88 days",
"59 days", mercuryPhoto)
```

To access a property of an photo object, your scripts then have to assemble a reference that works its way through the connection with the planet object:

```
copyrightData = Mercury.photo.copyright
```

The potential of custom objects of this type is enormous. For example, you can embed all the copy elements and image URLs for an online catalog in a single document. As the user selects items to view (or cycles through them in sequence), a

new JavaScript-written page displays the information in an instant. This requires only the image to be downloaded — unless the image was precached, as described in the image object discussion in Chapter 18. In this case, everything works instantaneously — no waiting for page after page of catalog.

If, by now, you think you see a resemblance between this object-within-an-object construction and a relational database, give yourself a gold star. Nothing prevents multiple objects from having the same subobject as their properties — like multiple business contacts having the same company object property.

More ways to create objects

The examples in Listings 41-5 and 41-6 show a way of creating objects that works with all scriptable browsers. If your audience is limited to users with more modern browsers, additional ways of creating custom objects exist.

From NN3+ and IE4+, you can use the new `Object()` constructor to generate a blank object. From that point on, you can define property and method names by simple assignment, as in the following:

```
var Earth = new Object()
Earth.diameter = "7920 miles"
Earth.distance = "93 million miles"
Earth.year = "365.25"
Earth.day = "24 hours"
Earth.showPlanet = showPlanet // function reference
```

When you create a lot of like-structured objects, the custom object constructor shown in Listing 41-6 is more efficient. But for single objects, the new `Object()` constructor is more efficient.

NN4+ and IE4+ scripters can also benefit from a shortcut literal syntax for creating a new object. You can set pairs of property names and their values inside a set of curly braces, and you can assign the whole construction to a variable that becomes the object name. The following script shows how to organize this kind of object constructor:

```
var Earth = {diameter:"7920 miles", distance:"93 million miles", year:"365.25",
            day:"24 hours", showPlanet:showPlanet}
```

Colons link name/value pairs, and commas separate multiple name/value pairs. The value portion of a name/value pair can even be an array (using the `[...]` constructor shortcut) or a nested object (using another pair of curly braces). In fact, you can nest arrays and objects to your heart's content to create exceedingly complex objects. All in all, this is a very compact way to embed data in a page for script manipulation. If your CGI, XML, and database skills are up to the task, consider using a server program to convert XML data into this compact JavaScript version with each XML record being its own JavaScript object. For multiple records, assign the curly-braced object definitions to an array entry. Then your scripts on the client can iterate through the data and generate the HTML to display the data in a variety of forms and sorted according to different criteria (thanks to the JavaScript array-sorting powers).

Object watcher methods

NN4+ includes two special functions for objects that were designed primarily for use with external debugging tools: `watch()` and `unwatch()`. The `watch()` method instructs JavaScript to keep an eye on a particular property in an object (any JavaScript-accessible object) and execute a function when the value of the property changes by assignment (that is, not by user interaction).

You can see how this works in the simplified example of Listing 41-7. Three buttons set the `value` property of a text box. You can turn on the `watch()` method, which calls a handler and passes the name of the property, the old value, and the new value. An alert in the listing's function demonstrates what those values contain.

Listing 41-7: Object Watching in NN4+

```
<HTML>
<HEAD>
<TITLE>Object Watching</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
function setIt(msg) {
    document.forms[0].entry.value = msg
}
function watchIt(on) {
    var obj = document.forms[0].entry
    if (on) {
        obj.watch("value",report)
    } else {
        obj.unwatch("value")
    }
}
function report(id, oldval, newval) {
    alert("The field's " + id + " property on its way from \n'" + oldval +
"\n to \n'" + newval + "'.")
    return newval
}
</SCRIPT>
<BODY>
<B>Watching Over You</B>
<HR>
<FORM>
Enter text here:
<INPUT TYPE="text" NAME="entry" SIZE=50 VALUE="Default Value"><P>
<INPUT TYPE="button" VALUE="Set to Phrase 1" onClick="setIt('Four score and
seven years ago...')"><BR>
<INPUT TYPE="button" VALUE="Set to Phrase 2" onClick="setIt('When in the course
of human events...')"><BR>
<INPUT TYPE="reset" onClick="setIt('Default Value')"><P>
<INPUT TYPE="button" VALUE="Watch It" onClick="watchIt(true)">
<INPUT TYPE="button" VALUE="Don't Watch It" onClick="watchIt(false)">
</FORM>
</BODY>
</HTML>
```

Better ways exist to intercept and preprocess user input, but the `watch()` function can be a helpful debugging tool when you want to monitor the hidden workings of scripts.

Defining object property getters and setters

A future version of the ECMA-262 language specification will likely include a pair of facilities called *getter* and *setter*. Until such time as the formal syntax is finalized, you can begin to experiment with this technique in NN6 using temporary syntax that adheres to the likely format (but intentionally uses different keywords until the standard is adopted). When the standard is adopted, a subsequent version of NN will include the standard keywords.

I introduced the idea of creating a getter and setter for an object briefly in Chapter 14, where the NN6 syntax style extended properties of some W3C DOM objects to include some of the Microsoft-specific (and very convenient) DOM syntax. Most notably, you can define a getter for any container to return an array of nested elements just like the IE-only `document.all` collection.

The purpose of a getter is to assign a new property to the prototype of an object and to define how the value returned by the property should be evaluated. A setter does the same, but it also defines how a new value assigned to the property should apply the value to the object. Both definitions are written in the form of anonymous functions, such that reading or writing an object's property value can include sophisticated processing for either operation.

Getters and setters are assigned to the `prototype` property of an object, thus enabling you to customize native and DOM objects. The NN6 syntax fashions getters, setters, and methods of an object's prototype with the following syntax:

```
object.prototype.__defineGetter__("propName", function)
object.prototype.__defineSetter__("propName", function)
```

Note that the underscores before and after the method names are actually pairs of underscore characters (that is, `__`, `__defineGetter`, `__`, `__`). This double underscore was chosen as a syntax that the ECMA standard will not use, so it will not conflict with the eventual syntax for this facility.

The first parameter of the method is the name of the property for which the getter or setter is defined. This can be an existing property name that you want to override. The second parameter can be a function reference; but more likely it will be an anonymous function defined in place. By using an anonymous function, you can take advantage of the context of the object for which the property is defined. For each property, define both a getter and setter — even if the property is meant to be read-only or write-only.

To see how this mechanism works, let's use the getter and setter shown in Chapter 14 to add an `innerText` property to HTML elements in NN6. This property is read/write, so functions are defined for both the getter and setter. The getter definition is as follows:

```
HTMLDivElement.prototype.__defineGetter__("innerText", function () {
    var rng = document.createRange()
    rng.selectNode(this)
    return rng.toString()
})
```

The modified object is the basic `HTMLElement` object—the object that NN6 uses to create instances of every HTML element for the page. After the statement above executes, every HTML element on the page inherits the new `innerText` property. Each time the `innerText` property is read for an element, the anonymous function in this getter executes. Thus, after a text range object is created, the range is set to the node that is the current element. This is an excellent example of how the context of the current object allows the use of the `this` keyword to refer to the very same object. Finally, the string version of the selected range is returned. It is essential that a getter function include a `return` statement and that the returned value is of the desired data type. Also take notice of the closing of the function's curly brace and the getter method's parenthesis.

By executing this function each time the property is read, the getter always returns the current state of the object. If content of the element has changed since the page loaded, you are still assured of getting the current text inside the element. This is far superior to simply running the statements inside this function once as the page loads to capture a static view of the element's text.

The corresponding setter definition is as follows:

```
HTMLElement.prototype.__defineSetter__("innerText", function (txt) {
    var rng = document.createRange()
    rng.selectNodeContents(this)
    rng.deleteContents()
    var newText = document.createTextNode(txt)
    this.appendChild(newText)
    return txt
})
```

To assign a value to an object's property, the setter function requires that a parameter variable receive the assigned value. That parameter variable plays a role somewhere within the function definition. For this particular setter, the current object (`this`) also manipulates the text range object. The contents of the current element are deleted, and a text node comprising the text passed as a parameter is inserted into the element. To completely simulate the IE behavior of setting the `innerText` property, the text is returned. While setters don't always return values, this one does so that the expression that assigns a value to the `innerText` property evaluates to the new text.

If you want to create a read-only property, you still define a setter for the property but you also assign an empty function, as in:

```
Node.prototype.__defineSetter__("all", function() {})
```

This prevents assignment statements to a read-only property from generating errors. A write-only property should also have a getter that returns `null` or an empty string, as in:

```
HTMLElement.prototype.__defineGetter__("outerHTML", function() {return ""})
```

Because the getter and setter syntax shown here is unique to NN6, you must obviously wrap such statements inside object detection or browser version detection statements. And, to reiterate, this syntax will change in future browser versions once ECMA adopts the formal syntax.

Using custom objects

There is no magic to knowing when to use a custom object instead of an array in your application. The more you work with and understand the way custom objects work, the more likely you will think about your data-carrying scripts in these terms—especially if an object can benefit from having one or more methods associated with it. This avenue is certainly not one for beginners, but I recommend that you give custom objects more than a casual perusal once you gain some JavaScripting experience.

Object-Oriented Concepts

As stated several times throughout this book, JavaScript is object-based rather than object-oriented. Instead of adhering to the class, subclass, and inheritance schemes of object-oriented languages such as Java, JavaScript uses what is called *prototype inheritance*. This scheme works not only for native and DOM objects but also for custom objects.

Adding a prototype

A custom object is frequently defined by a constructor function, which typically parcels out initial values to properties of the object, as in the following example:

```
function car(plate, model, color) {
    this.plate = plate
    this.model = model
    this.color = color
}
var car1 = new car("AB 123", "Ford", "blue")
```

NN4+ and IE4+ offer a handy shortcut, as well, to stuff default values into properties if none are provided (the supplied value is `null`, `0`, or an empty string). The OR operator (`|`) can let the property assignment statement apply the passed value, if present, or a default value you hard-wire into the constructor. Therefore, you can modify the preceding function to offer default values for the properties:

```
function car(plate, model, color) {
    this.plate = plate || "missing"
    this.model = model || "unknown"
    this.color = color || "unknown"
}
var car1 = new car("AB 123", "Ford", "")
```

After the preceding statements run, the `car1` object has the following properties:

```
car1.plate    // value = "AB 123"
car1.model    // value = "Ford"
car1.color    // value = "unknown"
```

If you then add a new property to the constructor's `prototype` property, as in

```
car.prototype.companyOwned = true
```

any `car` object you already created or are about to create automatically inherits the new `companyOwned` property and its value. You can still override the value of the `companyOwned` property for any individual `car` object. But if you don't override the property for instances of the `car` object, the `car` objects whose `companyOwned` property is not overridden automatically inherit any change to the prototype `companyOwned` value. This has to do with the way JavaScript looks for prototype property values.

Prototype inheritance

Each time your script attempts to read or write a property of an object, JavaScript follows a specific sequence in search of a match for the property name. The sequence is as follows:

1. If the property has a value assigned to the current (local) object, this is the value to use.
2. If there is no local value, check the value of the property's prototype of the object's constructor.
3. Continue up the prototype chain until either a match of the property is found (with a value assigned to it) or the search reaches the native `Object` object.

Therefore, if you change the value of a constructor's prototype property and you do not override the property value in an instance of that constructor, JavaScript returns the current value of the constructor's prototype property.

Nested objects and prototype inheritance

When you begin nesting objects, especially when one object invokes the constructor of another, there is an added wrinkle to the prototype inheritance chain. Let's continue with the `car` object defined earlier. In this scenario, consider the `car` object to be akin to a root object that has properties shared among two other types of objects. One of the object types is a company fleet vehicle, which needs the properties of the root `car` object (`plate`, `model`, `color`) but also adds some properties of its own. The other object that shares the `car` object is an object representing a car parked in the company garage—an object that has additional properties regarding the parking of the vehicle. This explains why the `car` object is defined on its own.

Now look at the constructor function for the parking record, along with the constructor for the basic `car` object:

```
function car(plate, model, color) {
    this.plate = plate || "missing"
    this.model = model || "unknown"
    this.color = color || "unknown"
}
function carInLot(plate, model, color, timeIn, spaceNum) {
    this.timeIn = timeIn
    this.spaceNum = spaceNum
    this.carInfo = car
    this.carInfo(plate, model, color)
}
```

The `carInLot` constructor not only assigns values to its unique properties (`timeIn` and `spaceNum`), but it also includes a reference to the `car` constructor arbitrarily assigned to a property called `carInfo`. This property assignment is merely a conduit that allows property values intended for the `car` constructor to be passed within the `carInLot` constructor function. To create a `carInLot` object, use a statement like the following:

```
var car1 = new carInLot("AA 123", "Ford", "blue", "10:02AM", "31")
```

After this statement, the `car1` object has the following properties and values:

```
car1.timeIn      // value = "10:02AM"
car1.spaceNum    // value = "31"
car1.carInfo     // value = reference to car object constructor function
car1.plate       // value = "AA 123"
car1.model       // value = "Ford"
car1.color       // value = "blue"
```

Let's say that five `carInLot` objects are created in the script (`car1` through `car5`). The prototype wrinkle comes into play if, for example, you assign a new property to the `car` constructor prototype:

```
car.prototype.companyOwned = true
```

Even though the `carInLot` objects use the `car` constructor, the instances of `carInLot` objects do not have a prototype chain back to the `car` object. As the preceding code stands, even though you've added a `companyOwned` property to the `car` constructor, no `carInLot` object inherits that property (even if you were to create a new `carInLot` object after defining the new prototype property for `car`). To get the `carInLot` instances to inherit the `prototype.companyOwned` property, you must explicitly connect the prototype of the `carInLot` constructor to the `car` constructor prior to creating instances of `carInLot` objects:

```
carInLot.prototype = new car()
```

The complete sequence, then, is as follows:

```
function car(plate, model, color) {
    this.plate = plate || "missing"
    this.model = model || "unknown"
    this.color = color || "unknown"
}
function carsInLot(plate, model, color, timeIn, spaceNum) {
    this.timeIn = timeIn
    this.spaceNum = spaceNum
    this.carInfo = car
    this.carInfo(plate, model, color)
}
carsInLot.prototype = new car()
var car1 = new carsInLot("123ABC", "Ford", "blue", "10:02AM", "32")
car.prototype.companyOwned = true
```

After this stretch of code runs, the `car1` object has the following properties and values:

```

carl.timeIn           // value = "10:02AM"
carl.spaceNum        // value = "31"
carl.carInfo         // value = reference to car object constructor function
carl.plate           // value = "AA 123"
carl.model           // value = "Ford"
carl.color           // value = "blue"
carl.companyOwned   // value = true

```

NN4+ provides one extra, proprietary bit of syntax in this prototype world. The `__proto__` property (that's with double underscores before and after the word "proto") returns a reference to the object that is next up the prototype chain. For example, if you inspect the properties of `carl.__proto__` after the preceding code runs, you see that the properties of the object next up the prototype chain are as follows:

```

carl.__proto__.plate // value = "AA 123"
carl.__proto__.model // value = "Ford"
carl.__proto__.color // value = "blue"
carl.__proto__.companyOwned // value = true

```

This property can be helpful in debugging custom objects and prototype inheritance chain challenges, but the property is not part of the ECMA standard. Therefore, I discourage you from using the property in your production scripts.

Object Object

<i>Properties</i>	<i>Methods</i>
constructor	hasOwnProperty()
prototype	isPrototypeOf()
	propertyIsEnumerable()
	toLocaleString()
	toString()
	valueOf()

Syntax

Creating an object object:

```

function constructorName([arg1,...[,argN]]) {
    statement(s)
}
var objName = new constructorName(["argName1",...[, "argNameN"])
var objName = new Object()
var objName = {propName1:propVal1[, propName2:propVal2[,...N]]}

```

Accessing an object object properties and methods:

```
objectReference.property | method([parameters])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	(✓)	✓	✓	✓	(✓)	✓	✓	✓	✓

About this object

While it might sound like doubletalk, the `Object` object is a vital native object in the JavaScript environment. It is the root object on which all other native objects—such as `Date`, `Array`, `String`, and the like—are based. This object also provides the foundation for creating custom objects, as described earlier in this chapter.

By and large, your scripts do not access the properties of the native `Object` object. The same is true for many of its methods, such as `toString()` and `valueOf()`, which internally allow debugging alert dialog boxes (and `The Evaluator`) to display something when referring to an object or its constructor.

You can use a trio of methods, described next, in IE5.5 and NN6 to perform some inspection of the prototype environment of an object instance. They are of interest primarily to advanced scripters who are building extensive, simulated object-oriented applications.

Methods

`hasOwnProperty("propName")`

Returns: Boolean.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `hasOwnProperty()` method returns `true` if the current object instance has the property defined in its constructor or in a related constructor function. But if this property is defined externally, as via assignment to the object's prototype property, the method returns `false`.

Using the example of the `car` and `carInLot` objects from earlier in this chapter, the following expressions evaluate to `true`:

```
car1.hasOwnProperty("spaceNum")
car1.hasOwnProperty("model")
```

Even though the `model` property is defined in a constructor that is invoked by another constructor, the property belongs to the `car1` object. The following statement, however, evaluates to `false`:

```
car1.hasOwnProperty("companyOwned")
```

This property is defined by way of the prototype of one of the constructor functions and is not a built-in property for the object instance.

isPrototypeOf(*objRef*)

Returns: Boolean.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The `isPrototypeOf()` method is intended to reveal whether or not the current object has a prototype relation with an object passed as a parameter. In practice, the IE5.5 and NN6 versions of this method not only operate differently, but they also do not appear in either browser to report prototype relationships correctly between objects. If any updated information is available for this method within these browsers, I will post it to the *JavaScript Bible* Support Center at <http://www.dannyg.com/update.html>.

propertyIsEnumerable("propName")

Returns: Boolean.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

In the terminology of the ECMA-262 language specification, a value is enumerable if constructions such as the `for-in` property inspection loop (Chapter 39) can inspect it. Enumerable properties include values such as arrays, strings, and virtually every kind of object. According to the ECMA specification, this method is not supposed to work its way up the prototype chain. IE5.5 appears to adhere to this, whereas NN6 treats a property inherited from an object's prototype as a valid parameter value.

42

CHAPTER

Global Functions and Statements

In addition to all the objects and other language constructs described in the preceding chapters of this reference part of the book, several language items need to be treated on a global scale. These items apply to no particular objects (or any object), and you can use them anywhere in a script. If you read earlier chapters, you were introduced to many of these functions and statements. This chapter serves as a convenient place to highlight these all-important items that are otherwise easily forgotten. At the end of the chapter, note the brief introduction to several objects that are built into the Windows-only versions of Internet Explorer. Some of these objects have pointers to more details at Microsoft's Web site.

This chapter begins with coverage of the following global functions and statements that are part of the core JavaScript language:

<i>Functions</i>	<i>Statements</i>
<code>decodeURI()</code>	<code>// and /*...*/ (comment)</code>
<code>decodeURIComponent()</code>	<code>const</code>
<code>encodeURI()</code>	<code>var</code>
<code>encodeURIComponent()</code>	
<code>escape()</code>	
<code>eval()</code>	
<code>isFinite()</code>	
<code>isNaN()</code>	
<code>Number()</code>	
<code>parseFloat()</code>	
<code>parseInt()</code>	
<code>toString()</code>	
<code>unescape()</code>	
<code>unwatch()</code>	
<code>watch()</code>	

In This Chapter

Converting strings into object references

Creating URL-friendly strings

Adding comments to scripts

Global functions are not tied to the document object model. Instead, they typically enable you to convert data from one type to another type. The list of global statements is short, but a couple of them appear extensively in your scripting.

Functions

```
decodeURI("encodedURI")
decodeURIComponent("encodedURIComponent")
encodeURI("URIString")
encodeURIComponent("URIComponentString")
```

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

The ECMA-262 Edition 3 standard, as implemented in IE5.5 and NN6, provides utility functions that perform a more rigorous conversion of strings to valid URI strings and vice versa than was achieved earlier via the `escape()` and `unescape()` functions (described later in this chapter). The purpose of the encoding functions is to convert any string to a version that you can use as a Uniform Resource Identifier, such as a Web page address or an invocation of a server CGI script. While Latin alphanumeric characters pass through the encoding process untouched, you must use the encoding functions to convert some symbols and other Unicode characters to a form (hexadecimal representations of the character numbers) that the Internet can pass from place to place. The space character, for example, must be encoded to its hex version: `%20`.

Perhaps the biggest difference between the `encodeURI()` and `escape()` functions (and their `decodeURI()` and `unescape()` counterparts) is that the more modern versions do not encode a wide range of symbols that are perfectly acceptable as URI characters according to the syntax recommended in RFC2396 (<http://www.ietf.org/rfc/rfc2396.txt>). Thus, the following characters are not encoded via the `encodeURI()` function:

```
; / ? : @ & = + $ , - _ . ! ~ * ' ( ) #
```

Use the `encodeURI()` and `decodeURI()` functions only on complete URIs. Applicable URIs can be relative or absolute, but these two functions are wired especially so symbols that are part of the protocol (`://`), search string (`?` and `=`, for instance), and directory level delimiters (`/`) are not encoded. The `decodeURI()` function should work with URIs that arrive from servers as page locations, but be aware that some server CGIs encode spaces into plus symbols (`+`) that are not decoded back to spaces by the JavaScript function. If the URIs your script needs to decode contain plus symbols in place of spaces, you need to run your decoded URI through a string replacement method to finish the job (regular expressions come in

handy here). If you are decoding URI strings that your scripts encoded, use the decode functions only on URIs that were encoded via the corresponding encode function. Do not attempt to decode a URI that was created via the old `escape()` function because the conversion processes work according to different rules.

The difference between a URI and a URI component is that a *component* is a single piece of a URI, generally not containing delimiter characters. For example, if you use the `encodeURIComponent()` function on a complete URI, almost all of the symbols (other than things such as periods) are encoded into hexadecimal versions—including directory delimiters. Therefore, you should use the component-level conversion functions only on quite granular pieces of a URI. For example, if you assemble a search string that has a name/value pair, you can use the `encodeURIComponent()` function separately on the name and on the value. But if you use that function on the pair that is already in the form *name=value*, the function encodes the equal symbol to a hexadecimal equivalent.

Use The Evaluator (Chapter 13) to experiment with the differences between encoding a full URI and a component and encoding and escaping a URI string. For example, compare the results of the following three statements:

```
escape("http://www.giantco.com/index.html?code=42")
encodeURIComponent("http://www.giantco.com/index.html?code=42")
encodeURIComponent("http://www.giantco.com/index.html?code=42")
```

Because the sample URI string is valid as is, the `encodeURIComponent()` version makes no changes. Experiment further by making the search string value into a string with a space, and see how each function treats that character.

```
escape("URIStrIng" [,1])
unescape("escapedURIStrIng")
```

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

If you watch the content of the Location field in your browser, you may occasionally see URLs that include a lot of % symbols plus some numbers. The format you see is *URL encoding* (more accurately called *URI encoding*—Uniform Resource Identifier rather than Uniform Resource Locator). This format allows even multiple word strings and nonalphanumeric characters to be sent as one contiguous string of a very low, common-denominator character set. This encoding turns a character, such as a space, into its hexadecimal equivalent value preceded by a percent symbol. For example, the space character (ASCII value 32) is hexadecimal 20, so the encoded version of a space is %20.

All characters, including tabs and carriage returns, can be encoded in this way and sent as a simple string that can be decoded on the receiving end for reconstruction. You can also use this encoding to preprocess multiple lines of text that must be stored as a character string in databases. To convert a plain-language

string to its encoded version, use the `escape()` method. This function returns a string consisting of the encoded version. For example:

```
var theCode = escape("Hello there")
// result: "Hello%20there"
```

Most, but not all, nonalphanumeric characters are converted to escaped versions with the `escape()` function. One exception is the plus sign, which URLs use to separate components of search strings. If you must encode the plus symbol, too, then add the optional second parameter to the function to make the plus symbol convert to its hexadecimal equivalent (2B):

```
var a = escape("Adding 2+2")
// result: "Adding%202+2"
var a = escape("Adding 2+2",1)
// result: "Adding%202%2B2"
```

To convert an escaped string back into plain language, use the `unescape()` function. This function returns a string and converts all URL-encoded strings—including those encoded with the optional parameter.

The `escape()` function operates in a way that is approximately midway between the newer functions `encodeURIComponent()` and `encodeURIComponent()`. The `escape()` function is best used on portions of URIs, such as the search string. If your scripts bounce back and forth between escaped and unescaped strings, be sure to balance the functions of the same type; use `unescape()` only on URI strings that are encoded via the `escape()` function.

Finally, be aware of slightly different behavior with regard to the @ symbol in various browsers. This character is not encoded in IE, but it is encoded (to %40) in NN.

`eval("string")`

Returns: Object reference.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Expression evaluation, as you probably are well aware by now, is an important concept to grasp in scripting with JavaScript (and programming in general). An expression evaluates to some value. But occasionally you need to force an additional evaluation on an expression to receive the desired results. The `eval()` function acts on a string value to force an evaluation of that string expression.

Perhaps the most common application of the `eval()` function is to convert a string version of an object reference to a genuine object reference. For example, one technique for creating a Dynamic HTML script that accommodates the different ways that IE and NN4 reference positionable objects is to assemble references out of the comparable pieces of references. In the following function, the name of a positionable object is passed as a parameter. This example assumes that global

variable flags are set elsewhere for `isNav4` and `isIE4`. The function must create a valid reference to the object depending on which browser the user runs:

```
function getReference(objName) {
    if (navigator.appVersion.charAt(0) == "4") {
        if (navigator.appName == "Netscape") {
            var range = ""
            var styleObj = ""
        } else {
            var range = ".all"
            var styleObj = ".style"
        }
        var theObj = eval("document" + range + "." + objName + styleObj)
        return theObj
    }
    return null
}
```

In the NN4 branch of the preceding example, the variables `range` and `styleObj` are assigned empty strings; for the Microsoft branch, each variable assumes the components that must be inserted into an object reference for the Microsoft syntax. If the components are concatenated without the `eval()` function, the result simply is a concatenated string (which is not the same as the object reference). By forcing an additional evaluation with the `eval()` function, the script invokes JavaScript to see if one more level of evaluation is needed. If JavaScript finds that the evaluation of that string is a valid object reference, it returns the reference as the result; otherwise, the function returns `undefined`.

The `eval()` function can evaluate any JavaScript statement or expression stored as a string. This includes string equivalents of arithmetic expressions, object value assignments, and object method invocation.

I do not recommend that you rely on the `eval()` function, however, because this function is inherently inefficient (from the standpoint of performance). Fortunately, you may not need the `eval()` function to get from a string version of an object's name to a valid object reference. For example, if your script loops through a series of objects whose names include serial numbers, you can use the object names as array indices rather than use `eval()` to assemble the object references. The inefficient way to set the value of a series of fields named `data0`, `data1`, and so on, is as follows:

```
function fillFields() {
    var theObj
    for (var i = 0; i < 10; i++) {
        theObj = eval("document.forms[0].data" + i)
        theObj.value = i
    }
}
```

A more efficient way is to perform the concatenation within the index brackets for the object reference:

```
function fillFields() {
    for (var i = 0; i < 10; i++) {
        document.forms[0].elements["data" + i].value = i
    }
}
```

**Tip**

Whenever you are about to use an `eval()` function, look for ways to use string index values of arrays of objects instead. The W3C DOM (in IE5+ and NN6) makes it even easier with the help of the `document.getElementById()` method, which takes a string as a parameter and returns a reference to the named object.

`isFinite(number)`

Returns: Boolean.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓			✓	✓	✓

It is unlikely that you will ever need the `isFinite()` function, but its purpose is to advise whether a number is beyond the absolute minimum or maximum values that JavaScript can handle. If a number is outside of that range, the function returns `false`. The parameter to the function must be a number data type.

`isNaN(expression)`

Returns: Boolean.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	(✓)	✓	✓	✓	✓	✓	✓	✓	✓

For those instances in which a calculation relies on data coming from a text field or other string-oriented source, you frequently need to check whether the value is a number. If the value is not a number, the calculation may result in a script error.

Use the `isNaN()` function to test whether a value is a number prior to passing the value onto the operation. The most common use of this function is to test the result of a `parseInt()` or `parseFloat()` function. If the strings submitted for conversion to those functions cannot be converted to a number, the resulting value is `NaN` (a special symbol indicating “not a number”). The `isNaN()` function returns `true` if the value is not a number.

A convenient way to use this function is to intercept improper data before it can do damage, as follows:

```
function calc(form) {
    var inputValue = parseInt(form.entry.value)
    if (isNaN(inputValue)) {
        alert("You must enter a number to continue.")
    } else {
        statements for calculation
    }
}
```

Probably the biggest mistake scripters make with this function is failing to observe the case of all the letters in the function name. The trailing uppercase “N” is easy to miss.

Note

The `isNaN()` function works in Navigator 2 only on UNIX platforms. It is available on all platforms in Navigator 3+ and Internet Explorer 3+.

```
Number("string")
parseFloat("string")
parseInt("string" [,radix])
```

Returns: Number.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	(✓)	(✓)	✓	✓	(✓)	(✓)	✓	✓	✓

All three of these functions convert a string value into a numeric value. The `parseInt()` and `parseFloat()` functions are compatible across all versions of all browsers; the `Number()` function is new with NN4 and IE4.

Use the `Number()` function when your script is not concerned with the precision of the value and prefers to let the source string govern whether the returned value is a floating-point number or an integer. The function takes a single parameter — a string to convert to a number value.

The `parseFloat()` function also lets the string source value determine whether the returned value is a floating-point number or an integer. If the source string includes any non-zero value to the right of the decimal, the result is a floating-point number. But if the string value were, say, "3.00", the returned value would be an integer value.

An extra, optional parameter for `parseInt()` enables you to define the number base for use in the conversion. If you don't specify a radix parameter, JavaScript tries to look out for you; but in doing so, JavaScript may cause some difficulty for you. The primary problem arises when the string parameter for `parseInt()` starts with a zero, which a text box entry or database field might do. In JavaScript, numbers starting with zero are treated as octal (base-8) numbers. Therefore, `parseInt("010")` yields the decimal value 8.

When you apply the `parseInt()` function, always specify the radix of 10 if you are working in base-10 numbers. You can, however, specify any radix value from 2 through 36. For example, to convert a binary number string to its decimal equivalent, assign a radix of 2 as follows:

```
var n = parseInt("011",2)
// result: 3
```

Similarly, you can convert a hexadecimal string to its decimal equivalent by specifying a radix of 16:

```
var n = parseInt("4F",16)
// result: 79
```

Both `parseInt()` and `parseFloat()` exhibit a very useful behavior: If the string passed as a parameter starts with at least one number followed by, say, letters, the functions do their jobs on the numeric part of the string and ignore the rest. This is why you can use `parseFloat()` on the `navigator.appVersion` string to extract just the reported version number without having to parse the rest of the string. For example, NN6 for Windows reports a `navigator.appVersion` value as

```
5.0 (Windows; en-US)
```

But you can get just the numeric part of the string via `parseFloat()`:

```
var ver = parseFloat(navigator.appVersion)
```

Because the result is a number, you can perform numeric comparisons to see, for instance, whether the version is greater than or equal to 4.

`toString([radix])`

Returns: String.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	(✓)	✓	✓	✓	(✓)	✓	✓	✓	✓

Every JavaScript core language object and every DOM document object has a `toString()` method associated with it. This method is designed to render the contents of the object in as meaningful a way as possible. Table 42-1 shows the result of applying the `toString()` method on each of the convertible core language object types.

Table 42-1 `toString()` Method Results for Object Types

<i>Object Type</i>	<i>Result</i>
String	The same string
Number	String equivalent (but numeric literals cannot be converted)
Boolean	"true" or "false"
Array	Comma-delimited list of array contents (with no spaces after commas)
Function	Decompiled string version of the function definition

Many DOM objects can be converted to a string. For example, a `location` object returns its URL. But when an object has nothing suitable to return for its content as a string, it usually returns a string in the following format:

```
[object objectType]
```

The `toString()` method is available on all versions of all browsers. However, a convenient improvement to `toString()` for NN3 and IE3/J2 is the optional `radix`

parameter. By setting this parameter between 2 and 16, you can convert numbers to string equivalents in different number bases. Listing 42-1 calculates and draws a conversion table for decimal, hexadecimal, and binary numbers between 0 and 20. In this case, the source of each value is the value of the index counter variable each time the for loop's statements execute.

Listing 42-1: Using toString() with Radix Values

```
<HTML>
<HEAD>
<TITLE>Number Conversion Table</TITLE>
</HEAD>
<BODY>
<B>Using toString() to convert to other number bases:</B>
<HR>
<TABLE BORDER=1>
<TR>
<TH>Decimal</TH><TH>Hexadecimal</TH><TH>Binary</TH></TR>
<SCRIPT LANGUAGE="JavaScript">
var content = ""
for (var i = 0; i <= 20; i++) {
    content += "<TR>"
    content += "<TD>" + i.toString(10) + "</TD>"
    content += "<TD>" + i.toString(16) + "</TD>"
    content += "<TD>" + i.toString(2) + "</TD></TR>"
}
document.write(content)
</SCRIPT>
</TABLE>
</BODY>
</HTML>
```

The `toString()` method of user-defined objects does not convert the object into a meaningful string, but you can create your own method to do just that. For example, if you want to make your custom object's `toString()` method behave like an array's method, then define the action of the method and assign that function to a property of the object (as shown in Listing 42-2).

Listing 42-2: Creating a Custom toString() Method

```
<HTML>
<HEAD>
<TITLE>Custom toString()</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function customToString() {
    var dataArray = new Array()
    var count = 0
    for (var i in this) {
        dataArray[count++] = this[i]
    }
}
```

Continued

Listing 42-2 (continued)

```

        if (count > 2) {
            break
        }
    }
    return dataArray.join(",")
}
var book = {title:"The Aeneid", author:"Virgil", pageCount:543}
book.toString = customToString
</SCRIPT>
</HEAD>
<BODY>
<B>A user-defined toString() result:</B>
<HR>
<SCRIPT LANGUAGE="JavaScript">
document.write(book.toString())
</SCRIPT>
</BODY>
</HTML>

```

When you run Listing 42-2, you can see how the `custom` object's `toString()` handler extracts the values of all elements of the object except for the last one, which is the function handler reference. You can customize how the data should be labeled and/or formatted.

`unwatch(property)`
`watch(property, handler)`

Returns: Nothing.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓	✓					

To supply the right kind of information to external debuggers, JavaScript in NN4+ implements two global functions that belong to every object—including user-defined objects. The `watch()` function keeps an eye on a desired object and property. If that property is set by assignment, the function invokes another user-defined function that receives information about the property name, its old value, and its new value. The `unwatch()` function turns off the `watch` functionality for a particular property. See Listing 41-7 in Chapter 41 for an example of how to use these functions that you can assign to any object.

Statements

```
//
/* ... */
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Comments are statements that the JavaScript interpreter (or server-side compiler) ignores. However, these statements enable authors to leave notes about how things work in their scripts. While lavish comments are useful to authors during a script's creation and maintenance, the full content of a client-side comment is downloaded with the document. Every byte of non-operational content of the page takes a bit more time to download. Still, I recommend lots of comments—particularly as you create a script.

JavaScript offers two styles of comments. One style consists of two forward slashes (no spaces between them). JavaScript ignores any characters to the right of those slashes on the same line, even if they appear in the middle of a line. You can stack as many lines of these single-line comments as is necessary to convey your thoughts. I typically place a space between the second slash and the beginning of my comment. The following are examples of valid, one-line comment formats:

```
// this is a comment line usually about what's to come
var a = "Fred" // a comment about this line
// You may want to capitalize the first word of a comment
// sentence if it runs across multiple lines.
//
// And you can leave a completely blank line, like the one above.
```

For longer comments, it is usually more convenient to enclose the section in the other style of comment. The following comment opens with a forward slash and asterisk (/*) and ends with an asterisk and forward slash (*). JavaScript ignores all statements in between—including multiple lines. If you want to comment out briefly a large segment of your script for debugging purposes, it is easiest to bracket the segment with these comment symbols. To make these comment blocks easier to find, I generally place these symbols on their own lines as follows:

```
/*
some
  commented-out
  statements
*/
```

If you are developing rather complex documents, you might find using comments a convenient way to help you organize segments of your scripts and make each

segment easier to find. For example, you can define a comment block above each function and describe what the function is about, as in the following example.

```
/*-----
   calculate()
   Performs a mortgage calculation based on
   parameters blah, blah, blah. Called by blah
   blah blah.
   -----*/
function calculate(form) {
    statements
}
```

const

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

The `const` keyword initializes a constant. Unlike a variable, whose data is subject to change while a page loads, a constant's value cannot be modified once it is assigned. It is common practice in many programming languages to define constant identifiers with all uppercase letters, usually with underscore characters to delimit multiple words. This style makes it easier to see a constant's application later in the program.

Listing 42-3 shows how you can use a constant. The page conveys temperature data for several cities. (Presumably, this data is updated on the server and fashioned into an array of data when the user requests the page.) For temperatures below freezing, the temperature is shown in a distinctive text style. Because the freezing temperature is a constant reference point, it is assigned as a constant.

Listing 42-3: Using the `const` Keyword

```
<HTML>
<HEAD>
<TITLE>const(ant)</TITLE>
<STYLE TYPE="text/css">
.cold {font-weight:bold; color:blue}
TD {text-align:center}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
const FREEZING_F = 32
var cities = ["London", "Moscow", "New York", "Tokyo", "Sydney"]
var tempsF = [33, 12, 20, 40, 75]
function showData() {
    var tableData = ""
    for (var i = 0; i < cities.length; i++) {
        tableData += "<TR><TD>" + cities[i] + "</TD><TD "
        tableData += (tempsF[i] < FREEZING_F) ? "CLASS='cold'" : ""
        tableData += ">" + tempsF[i] + "</TR>"
    }
}
```

```

    }
    document.getElementById("display").innerHTML = tableData
}
</SCRIPT>
</HEAD>
<BODY onLoad="showData()">
<H1>The const keyword</H1>
<HR>
<TABLE ID="temps">
<TR><TH>City<TH>Temperature</TR>
<TBODY ID="display">
</TBODY>
</TABLE>
</BODY>
</HTML>

```

The `const` keyword likely will be adopted in the next version of the ECMA-262 standard and will become part of the JavaScript vernacular in future browsers.

var

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

Before using any variable, you should declare it (and optionally initialize it with a value) via the `var` statement. If you omit the `var` keyword, the variable is automatically assigned as a global variable within the current document. To keep a variable local to a function, you must declare or initialize the variable with the `var` keyword inside the function's braces.

If you assign no value to a variable, it evaluates to `null`. Because a JavaScript variable is not limited to one variable type during its lifetime, you don't need to initialize a variable to an empty string or zero unless that initial value helps your scripting. For example, if you initialize a variable as an empty string, you can then use the add-by-value operator (`+=`) to append string values to that variable in a future statement in the document.

To save statement lines, you can declare and/or initialize multiple variables with a single `var` statement. Separate each `varName=value` pair with a comma, as in

```

var name, age, height // declare as null
var color="green", temperature=85.6 // initialize

```

Variable names (also known as identifiers) must be one contiguous string of characters, and the first character must be a letter. Many punctuation symbols are also banned, but the underscore character is valid and often is used to separate multiple words in a long variable name. All variable names (like most identifiers in JavaScript) are case-sensitive, so you must name a particular variable identically throughout the variable's scope.

IE/Windows Objects

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

Microsoft prides itself on the integration between Web browser functionality and the Windows operating system. The linkage between browser and OS is most apparent in IE's facilities for accessing ActiveX objects. Microsoft has fashioned several such objects for access to scripters — again, provided the deployment is intended only for Windows versions of Internet Explorer. Some objects also exist as a way to expose some Visual Basic Script (VBScript) functionality to JavaScript. Because these objects are more within the realm of Windows and ActiveX programming, the details and quirks of working with them from IE/Windows is best left to other venues. But in case you are not familiar with these facilities, the following discussions introduce the basic set of IE/Windows objects. You can find more details at the Microsoft Developer Network (MSDN) Web site; in addition, I provide appropriate URLs for your further exploration.

The objects mentioned here are the `ActiveXObject`, `Dictionary`, `Enumerator`, `FileSystemObject`, and `VBArray` objects. Microsoft documents these objects as if they are part of the native JScript language. However, you can be sure that they will remain proprietary certainly to Internet Explorer, if not exclusively for Windows-only versions.

ActiveXObject

`ActiveXObject` is a generic object that allows your script to open and access what Microsoft sometimes calls *automation objects*. An automation object is an executable program that might run on the client or be served from a server. This can include local applications, such as applications from the Microsoft Office suite, executable DLLs (dynamic-link libraries), and so on.

Use the constructor for the `ActiveXObject` to obtain a reference to the object according to the following syntax:

```
var objRef = new ActiveXObject(appName.className[, remoteServerName])
```

This JScript syntax is the equivalent of the VBScript `CreateObject()` method. You need to know a bit about Windows programming to determine the application name and the classes or types available for that application. For example, to obtain a reference to an Excel worksheet, use this constructor:

```
var mySheet = new ActiveXObject("Excel.Sheet")
```

Once you have a reference to the desired object, you must also know the names of the properties and methods of the object you'll be addressing. You can access much of this information via Microsoft's developer tools, such as Visual InterDev or the tools that come with Visual Basic. These tools enable you to query an object to discover its properties and methods. Unfortunately, an `ActiveXObject`'s properties are not enumerable through a typical JavaScript `for-in` property inspector.

Accessing an `ActiveXObject`, especially one on the client, involves some serious security considerations. The typical security setup for an IE client prevents scripts from accessing client applications, at least not without asking the user if it's okay to do so. While it's foolhardy to state categorically that you cannot perform surreptitious inspection or damage to a client without the user's knowledge (hackers find holes from time to time), it is highly unlikely. In a corporate environment, where some level of access to all clients is desirable, the client may be set up to accept instructions to work with ActiveX objects when they come from trusted sources. The bottom line is that unless you are well versed in Windows programming, don't expect the `ActiveXObject` to become some kind of magic portal that enables you to invade the privacy or security of unsuspecting users.

For more details, visit <http://msdn.microsoft.com/scripting/jscript/doc/jsobjActiveXObject.htm>.

Dictionary

While the `Dictionary` object is very helpful to VBScript authors, JavaScript already provides the equivalent functionality natively. A `Dictionary` object behaves very much like a JavaScript array that has string index values (similar to a Java hash table), although numeric index values are also acceptable in the `Dictionary`. Indexes are called *keys* in this environment. VBScript arrays do not have this facility natively, so the `Dictionary` object supplements the language for the sake of convenience. Unlike a JavaScript array, however, you must use the various properties and methods of the `Dictionary` object to add, access, or remove items from it.

You create a `Dictionary` object via `ActiveXObject` as follows:

```
var dict = new ActiveXObject("Scripting.Dictionary")
```

You must create a separate `Dictionary` object for each array. Table 42-2 lists the properties and methods of the `Dictionary` object. After you create a blank `Dictionary` object, populate it via the `Add()` method for each entry. For example, the following statements create a `Dictionary` object to store U.S. state capitals:

```
var stateCaps = new ActiveXObject("Scripting.Dictionary")
stateCaps.Add("Illinois", "Springfield")
```

You can then access an individual item via the `Key` property (which, thanks to its VBScript heritage, looks more like a JavaScript method). One convenience of the `Dictionary` object is the `Keys()` method, which returns an array of all the keys in the dictionary—something that a string-indexed JavaScript array could use.

Table 42-2 Dictionary Object Properties and Methods

<i>Property</i>	<i>Description</i>
<code>Count</code>	Integer number of entries in the dictionary (read-only)
<code>Item("key")</code>	Reads or writes a value for an entry whose name is <i>key</i>
<code>Key("key")</code>	Assigns a new key name to an entry

Continued

Table 42-2 (continued)

Method	Description
Add("key", value)	Adds a value associated with a unique key name
Exists("key")	Returns Boolean <i>true</i> if <i>key</i> exists in dictionary
Items()	Returns VBArray of values in dictionary
Keys()	Returns VBArray of keys in dictionary
Remove("key")	Removes <i>key</i> and its value
RemoveAll()	Removes all entries

For more details, visit <http://msdn.microsoft.com/scripting/jscript/doc/jsobjDictionary.htm>.

Enumerator

An `Enumerator` object provides JavaScript with access to collections that otherwise do not allow direct access to their items via index number or name. This object isn't necessary when working with DOM collections, such as `document.all`, because you can use the `item()` method to obtain a reference to any member of the collection. But if you are scripting ActiveX objects, some of these objects' methods or properties may return collections that cannot be accessed through this mechanism or the JavaScript `for-in` property inspection technique. Instead, you must wrap the collection inside an `Enumerator` object.

To wrap a collection in an `Enumerator`, invoke the constructor for the object, passing the collection as the parameter:

```
var myEnum = new Enumerator(someCollection)
```

This enumerator instance must be accessed via one of its four methods to position a "pointer" to a particular item and then extract a copy of that item. In other words, you don't access a member directly (that is, by diving into the collection with an item number to retrieve). Instead, you move the pointer to the desired position and then read the item value. As you can see from the list of methods in Table 42-3, this object is truly intended for looping through the collection. Pointer control is limited to positioning it at the start of the collection and incrementing its position along the collection by one:

```
myEnum.moveFirst()
for (; !myEnum.atEnd(); myEnum.moveNext()) {
    val = myEnum.item()
    // more statements that work on value
}
```

Table 42-3 Enumerator Object Methods

<i>Method</i>	<i>Description</i>
<code>atEnd()</code>	Returns <code>true</code> if pointer is at end of collection
<code>item()</code>	Returns value at current pointer position
<code>moveFirst()</code>	Moves pointer to first position in collection
<code>moveNext()</code>	Moves pointer to next position in collection

For more details, visit <http://msdn.microsoft.com/scripting/jscript/doc/jsobjEnumerator.htm>.

FileSystemObject

Of all the IE/Windows objects, the one whose capabilities most scripters want to have as a cross-browser native object is `FileSystemObject`. A common wish among scripters is to be able to save some user-entered data on the client in file form rather than as a cookie. Of course, there can't be wide-open access to the file system because unscrupulous scripters could wreak havoc with a user's system and privacy—especially in such a well-documented and constant OS file structure as Windows. Netscape Navigator can accomplish many of these same operations via direct access to Java classes and signed scripts (which obtain the user's permission before accessing the file system).

`FileSystemObject` has a large library of methods (and one property) that scripts with the proper security clearance and permission can use to read and write files, create and delete files and directories, and, essentially, have its way with the contents of the client's hard disk. Table 42-4 shows a summary of these methods.

Table 42-4 **FileSystemObject Property and Methods**

Property	Description
Drives	Returns a collection of (disk) <code>Drive</code> objects (a <code>Drive</code> object has 15 properties)
Method	Description
<code>BuildPath(path, name)</code>	Appends name to existing <code>path</code>
<code>CopyFile(src, dest[, overwrite])</code>	Copies file at <code>src</code> path to <code>dest</code> path, optionally to automatically overwrite existing <code>dest</code> file of same name
<code>CopyFolder(src, dest[, overwrite])</code>	Copies directory at <code>src</code> path to <code>dest</code> path, optionally to automatically overwrite existing <code>dest</code> directory of same name
<code>CreateFolder(path)</code>	Creates folder with name specified in <code>path</code>
<code>CreateTextFile(path[, overwrite[, unicode]])</code>	Returns <code>TextStream</code> object after opening an empty file at <code>path</code> , optionally to overwrite existing file at <code>path</code> and optionally to save characters in Unicode (instead of ASCII)
<code>DeleteFile(path[, force])</code>	Deletes file at <code>path</code> , optionally to force deletion of read-only file
<code>DeleteFolder(path[, force])</code>	Deletes directory at <code>path</code> , optionally to force deletion of read-only directory
<code>DriveExists(drivespec)</code>	Returns <code>true</code> if specified drive exists on client
<code>FileExists(filespec)</code>	Returns <code>true</code> if specified file exists
<code>FolderExists(folderspec)</code>	Returns <code>true</code> if specified directory exists
<code>GetAbsolutePathName(pathspec)</code>	Returns full path based on parameters supplied in <code>pathspec</code>
<code>GetBaseName(filespec)</code>	Returns base name of rightmost item in <code>filespec</code> but without file extension
<code>GetDrive(drivespec)</code>	Returns <code>Drive</code> object referenced by <code>drivespec</code> (for example, <code>c:\</code>)
<code>GetDriveName(path)</code>	Returns name of the drive for a given <code>path</code>
<code>GetExtensionName(path)</code>	Returns file extension for rightmost item in the <code>path</code>
<code>GetFile(filespec)</code>	Returns <code>File</code> object (a <code>File</code> object has 12 properties and 4 methods of its own)

Method	Description
<code>GetFileName(<i>filespec</i>)</code>	Returns the full filename of rightmost item in <i>pathspec</i>
<code>GetFileVersion(<i>filespec</i>)</code>	Returns version number associated with a file
<code>GetFolder(<i>folderspec</i>)</code>	Returns Folder object (a Folder object has 15 properties and 4 methods of its own)
<code>GetParentFolderName(<i>path</i>)</code>	Returns name of parent directory of <i>path</i>
<code>GetSpecialFolder(<i>type</i>)</code>	Returns Folder object of type 0 (Windows), 1 (Windows\System), or 2 (Windows\Temp)
<code>GetTempName()</code>	Returns a nonsense name for use as a temp filename
<code>MoveFile(<i>src</i>, <i>dest</i>)</code>	Moves <i>src</i> file(s) to <i>dest</i>
<code>MoveFolder(<i>src</i>, <i>dest</i>)</code>	Moves <i>src</i> folder(s) to <i>dest</i>
<code>OpenTextFile(<i>path</i>[, <i>iomode</i>[, <i>create</i>[, <i>format</i>]])</code>	Returns a TextStream object after opening a file at <i>path</i> for mode (ForReading, ForWriting, ForAppending); optionally to create file if not existing; optionally to treat characters as Unicode (TristateTrue), ASCII (TristateFalse), or system default (TristateUseDefault)

As for the basic task of writing some data to a hard disk, the sequence involves creating an instance of `FileSystemObject`, opening an output stream for text, writing content to the file, and closing the file. Such a sequence might look like the following:

```
function saveLocalData(theData) {
    var fsObj = new ActiveXObject("Scripting.FileSystemObject")
    var theFile = fsObj.CreateTextFile("c:\\giantco.txt", true)
    theFile.WriteLine(theData)
    theFile.Close()
}
```

The `WriteLine()` method belongs to the `TextStream` object, which is returned by `FileSystemObject`'s `CreateTextFile()` method. You can read more about the `TextStream` object and the details of the `FileSystemObject` at <http://msdn.microsoft.com/scripting/jscript/doc/jsobjtextstream.htm> and <http://msdn.microsoft.com/scripting/jscript/doc/jsobjFileSystem.htm>.

VBAArray

The `VBAArray` object provides JavaScript access to Visual Basic *safe arrays*. Such an array is read-only and is commonly returned by ActiveX objects. Such arrays can be composed in VBScript sections of client-side scripts. Visual Basic arrays by their

very nature can have multiple dimensions. For example, the following code creates a three-by-two VB array:

```
<SCRIPT LANGUAGE="VBScript">
Dim myArray(2, 1)
myArray(0, 0) = "A"
myArray(0, 1) = "a"
myArray(1, 0) = "B"
myArray(1, 1) = "b"
myArray(2, 1) = "C"
myArray(2, 2) = "c"
</SCRIPT>
```

Once you have a valid VB array, you can convert it to an object that the JScript interpreter can't choke on:

```
<SCRIPT LANGUAGE="JavaScript">
var theVBArray = new VBArray(myArray)
</SCRIPT>
```

Global variables from one script language block can be accessed by another block, even in a different language. But at this point, the array is not in the form of a JavaScript array yet. You can either convert it to such via the `VBArray.toArray()` method or access information about the `VBArray` object through its other methods (described briefly in Table 42-5). Once you convert a `VBArray` to a JavaScript array, you can then iterate through the values just like any JavaScript array.

Table 42-5 VBArray Object Methods

<i>Method</i>	<i>Description</i>
<code>dimensions()</code> original array	Returns number of dimensions of the original array
<code>getItem(dim1[, dim2[, ...dimN]])</code>	Returns value at array location defined by dimension addresses
<code>lbound(dim)</code>	Returns lowest index value for a given dimension
<code>toArray()</code>	Returns JavaScript array version of <code>VBArray</code>
<code>ubound(dim)</code>	Returns highest index value for a given dimension

When you use the `toArray()` method and the source array has multiple dimensions, values from dimensions after the first “row” are simply appended to the JavaScript array with no nesting structure. IE through version 5.5 provides no backward conversion from a JavaScript array to a VB array.

For more details, visit <http://msdn.microsoft.com/scripting/jscript/doc/jsobjVBArray.htm>.

Data-Entry Validation

Give users a field in which to enter data and you can be sure that some users will enter the wrong kind of data. Often the “mistake” is accidental — a slip of the pinkie on the keyboard; other times, users intentionally type the incorrect entry to test the robustness of your application. Whether you solicit a user’s entry for client-side scripting purposes or for input into a server-based CGI or database, you should use JavaScript on the client to handle validation of the user’s entry. Even for a form connected to a CGI script, it’s far more efficient (from the perspective of bandwidth, server load, and execution speed) to let client-side JavaScript get the data straight before your server program deals with it.

Real-Time Versus Batch Validation

You have two opportunities to perform data-entry validation in a form: as the user enters data into a form and just before the form is submitted. I recommend you take advantage of both of these opportunities.

Real-time validation triggers

The most convenient time to catch an error is immediately after the user makes it — especially for a long form that requests a wide variety of information. You can make the user’s experience less frustrating if you catch an entry mistake just after the user enters the information: his or her attention is already focused on the nature of the content (or some paper source material may already be in front of the user). It is much easier for the user to address the same information entry right away.

A valid question for the page author is how to trigger the real-time validation. Backward-compatible text boxes have two potential event handlers for this purpose: `onChange` and `onBlur`. I personally avoid `onBlur` event handlers, especially ones that can display an alert dialog box (as a data-entry validation is likely to do). Because a good validation routine brings focus to the errant text box, you can get some odd behavior with the interaction of the `focus()` method and the

In This Chapter

Validating data as it is being entered

Validating data immediately prior to submission

Organizing complex data-validation tasks

onBlur event handler. Users who wish to continue past an invalid field are locked in a seemingly endless loop.

The problem with using onChange as the validation trigger is that a user can defeat the validation. A change event occurs only when the text of a field indeed changes when the user tabs or clicks out of the field. If the user is alerted about some bad entry in a field and doesn't fix the error, the change event doesn't fire again. In some respects, this is good because a user may have a legitimate reason for passing by a particular form field initially with the intention of returning to the entry later. Because a user can defeat the onChange event handler trigger, I recommend you also perform batch validation prior to submission.

In NN4+ and IE4+, you also have the luxury of letting keyboard events trigger validations. This is most helpful when you want to prevent some character(s) from being entered into a field. For example, if a field is supposed to contain only a positive integer value, you can use the onKeyPress event handler of the text box to verify that the character just typed is a number. If the character is not a number, the event is trapped and no character reaches the text box. You should also alert the user in some way about what's going on. Listing 43-1 demonstrates a simplified version of this kind of keyboard trapping, compatible with NN4+ and IE4+ event models. The message to the user is displayed in the statusbar. Displaying the message there has the advantage of being less intrusive than an alert dialog box (and keeps the text insertion cursor in the text box), but it also means that users might not see the message. The onSubmit event handler in the listing prevents a press of the Enter key in this one-field form from reloading this sample page.

Listing 43-1: Allowing Only Numbers into a Text Box

```
<HTML>
<HEAD>
<TITLE>Letting Only Numbers Pass to a Form Field</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function checkIt(evt) {
    evt = (evt) ? evt : window.event
    var charCode = (evt.which) ? evt.which : evt.keyCode
    if (charCode > 31 && (charCode < 48 || charCode > 57)) {
        status = "This field accepts numbers only."
        return false
    }
    status = ""
    return true
}
</SCRIPT>
</HEAD>

<BODY>
<H1>Letting Only Numbers Pass to a Form Field</H1>
<HR>
<FORM onSubmit="return false">
Enter any positive integer: <INPUT TYPE="text" NAME="numeric"
    onKeyPress="return checkIt(event)">
</FORM>
</BODY>
</HTML>
```

Keyboard event monitoring isn't practical for most validation actions, however. For example, if the user is supposed to enter an e-mail address, you need to validate the complete entry for the presence of an @ symbol (via the `onChange` event handler). On the other hand, you can be granular about your validations and use both the `onChange` and `onKeyPress` event handlers; you employ the latter for blocking invalid characters in e-mail addresses (such as spaces).

Batch mode validation

In all scriptable browsers, the `onSubmit` event handler cancels the submission if the handler evaluates to return `false`. Additional submission event cancelers include setting the IE4+ `event.returnValue` property to `false` and invoking the `event.preventDefault()` method in NN6 (see Chapter 29 on event objects for details). You can see an example of the basic `return false` behavior in Listing 23-4 of Chapter 23. That example uses the results of a `window.confirm()` dialog box to determine the return value of the event handler. But you can also use a return value from a series of individual text box validation functions. If any one of the validations fails, the user is alerted and the submission is canceled.

Before you worry about two versions of validation routines loading down the scripts in your page, you'll be happy to know that you can reuse the same validation routines in both the real-time and batch validations. Later in this chapter, I demonstrate what I call "industrial-strength" data-entry validation adapted from a real intranet application. But before you get there, you should learn about general validation techniques that you can apply to both types of validations.

Designing Filters

The job of writing data-validation routines essentially involves designing filters that weed out characters or entries that don't fit your programming scheme. Whenever your filter detects an incorrect entry, it should alert the user about the nature of the problem and enable the user to correct the entry.

Before you put a text or `TEXTAREA` object into your document that invites users to enter data, you must decide if any possible entry can disturb the execution of the rest of your scripts. For example, if your script must have a number from that field to perform calculations, you must filter out any entry that contains letters or punctuation — except for periods if the program can accept floating-point numbers. Your task is to anticipate every possible entry users can make and allow only those entries your scripts can use.

Not every entry field needs a data-validation filter. For example, you may prompt a user for information that is eventually stored as a `document.cookie` or in a string database field on the server for future retrieval. If no further processing takes place on that information, you may not have to worry about the specific contents of that field.

One other design consideration is whether a text field is even the proper user interface element for the data required of the user. If the range of choices for a user entry is small (a dozen or fewer), a more sensible method is to avoid the data-entry problem altogether by turning that field into a `SELECT` element. Your HTML attributes for the object ensure that you control the kind of entry made to that object. As long as your script knows how to deal with each of the options defined for that object, you're in the clear.

Building a Library of Filter Functions

A number of basic data-validation processes function repeatedly in form-intensive HTML pages. Filters for integers only, numbers only, empty entries, alphabet letters only, and the like are put to use every day. If you maintain a library of generalizable functions for each of your data-validation tasks, you can drop these functions into your scripts at a moment's notice and be assured that they will work. For NN3+ and IE4+, you can also create the library of validation functions as a separate .js library file and link the scripts into any HTML file that needs them.

Making validation functions generalizable requires careful choice of wording and logic so that they return Boolean values that make syntactical sense when called from elsewhere in your scripts. As you see later in this chapter, when you build a larger framework around smaller functions, each function is usually called as part of an `if...else` conditional statement. Therefore, assign a name that fits logically as part of an `if` clause in plain language. For example, you can name a function that checks whether an entry is empty `isEmpty()`. The calling statement for this function is:

```
if (isEmpty(value)) { ... }
```

From a plain-language perspective, the expectation is that the function returns `true` if the passed value is empty. With this design, the statements nested in the `if` construction handle empty entry fields. I revisit this design later in this chapter when I start stacking multiple-function calls together in a larger validation routine.

To get you started with your library of validation functions, this chapter provides some building blocks that you can learn from and use as starting points for more specific filters of your own design. Some of these functions are put to use in the JavaScript application in Chapter 50.

`isEmpty()`

This first function, shown in Listing 43-2, checks to see if the incoming value is either empty or `null`. Adding a check for `null` means that you can use this function for purposes other than just text-object validation. For example, if another function defines three parameter variables, but the calling function passes only two, the third variable is set to `null`. If the script then performs a data-validation check on all parameters, the `isEmpty()` function responds that the `null` value is devoid of data.

Listing 43-2: Is an Entry Empty or Null?

```
// general purpose function to see if an input value has been
// entered at all
function isEmpty(inputStr) {
    if (inputStr == null || inputStr == "") {
        return true
    }
    return false
}
```

This function uses a Boolean OR operator (`|`) to test for the existence of a `null` value or an empty string in the value passed to the function. Because the name of the function implies a `true` response if the entry is empty, that value is the one that returns to the calling statement if either condition is true. Because a `return` statement halts further processing of a function, the `return false` statement lies outside of the `if` construction. If processing reaches this statement, the `inputStr` value has failed the test.

If this seems like convoluted logic — `return true` when the value is empty — you can also define a function that returns the inverse values. You can name it `isNotEmpty()`. As it turns out, however, typical processing of an empty entry is better served when the test returns a `true` than when the value is empty — aiding the `if` construction that calls the function in the first place.

isPosInteger()

This next function examines each character of the value to make sure that only numbers from 0 through 9 with no punctuation or other symbols exist. The goal of the function in Listing 43-3 is to weed out any value that is not a positive integer.

Listing 43-3: Test for Positive Integers

```
// general purpose function to see if a suspected numeric input
// is a positive integer
function isPosInteger(inputVal) {
    inputStr = inputVal.toString()
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i)
        if (oneChar < "0" || oneChar > "9") {
            return false
        }
    }
    return true
}
```

Notice that this function makes no assumption about the data type of the value that is passed as a parameter. If the value had come directly from a text object, it would already be a string and the line that forced data conversion to a string would be unnecessary. But to generalize the function, the conversion is included to accommodate the possibility that it may be called from another statement that has a numeric value to check.

The function requires you to convert the input value to a string because it performs a character-by-character analysis of the data. A `for` loop picks apart the value one character at a time. Rather than force the script to invoke the `string.charAt()` method twice for each time through the loop (inside the `if` condition), one statement assigns the results of the method to a variable, which is then used twice in the `if` condition. Placing the results of the `charAt()` method into a variable makes the `if` condition shorter and easier to read and also is microscopically more efficient.

In the `if` condition, the ASCII value of each character is compared against the range of 0 through 9. This method is safer than comparing numeric values of the single characters because one of the characters can be nonnumeric. (You can encounter all kinds of other problems trying to convert that character to a number for numeric comparison.) The ASCII value, on the other hand, is neutral about the meaning of a character: If the ASCII value is less than 0 or greater than 9, the character is not valid for a genuine positive integer. The function bounces the call with a false reply. On the other hand, if the `for` loop completes its traversal of all characters in the value without a hitch, the function returns `true`.

You may wonder why this validation function doesn't use the `parseInt()` global function (Chapter 42). That function returns `NaN` only if the first character of the input string is not a number. But because `parseInt()` and `parseFloat()` peel off any initial numeric values from a string, neither returns `NaN` if the input string is, for example, `35a`.

isInteger()

The next possibility includes the entry of a negative integer value. Listing 43-4 shows that you must add an extra check for a leading negation sign.

Listing 43-4: Checking for Leading Minus Sign

```
// general purpose function to see if a suspected numeric input
// is a positive or negative integer
function isInteger(inputVal) {
    inputStr = inputVal.toString()
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i)
        if (i == 0 && oneChar == "-") {
            continue
        }
        if (oneChar < "0" || oneChar > "9") {
            return false
        }
    }
    return true
}
```

When a script can accept a negative integer, the filter must enable the leading minus sign to pass unscathed. You cannot just add the minus sign to the `if` condition of Listing 43-3 because you can accept that symbol only when it appears in the first position of the value—anywhere else makes the value an invalid number. To handle the possibility of a leading minus sign, you add another `if` statement whose condition looks for a special combination: the first character of the string (as indexed by the loop-counting variable) and the minus character. If both of these conditions are met, execution immediately loops back around to the update expression of the `for` loop (because of the `continue` statement) rather than carrying out the second `if` statement, which would obviously fail. By putting the `i == 0` comparison operation at the front of the condition, you ensure the entire condition short circuits to `false` for all subsequent iterations through the loop.

isNumber()

The final numeric filter function in this series enables any integer or floating-point number to pass while filtering out all others (Listing 43-5). All that distinguishes an integer from a floating-point number for data-validation purposes is the decimal point.

Listing 43-5: Testing for a Decimal Point

```
// general purpose function to see if a suspected numeric input
// is a positive or negative number
function isNumber(inputVal) {
    oneDecimal = false
    inputStr = inputVal.toString()
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i)
        if (i == 0 && oneChar == "-") {
            continue
        }
        if (oneChar == "." && !oneDecimal) {
            oneDecimal = true
            continue
        }
        if (oneChar < "0" || oneChar > "9") {
            return false
        }
    }
    return true
}
```

Anticipating the worst, however, the function cannot simply treat a decimal point at any position within the string as a valid character. Such an act assumes that no one would ever enter more than one decimal point into a numeric text field. Only one decimal point is allowed for this function (as well as for JavaScript math). Therefore, you add a Boolean flag variable (`oneDecimal`) to the function and a separate `if` condition that sets that flag to `true` when the function encounters the first decimal point. Should another decimal point appear in the string, the final `if` statement gets a crack at the character. Because the character falls outside the ASCII range of 0 through 9, it fails the entire function.

If you want to accept only positive floating-point numbers, you can make a new version of this function by removing the statement that lets the leading minus sign through. Be aware that this function works only for values that are not represented in exponential notation.

Custom validation functions

The listings shown so far in this chapter should give you plenty of source material to use in writing customized validation functions for your applications. Listing 43-6 shows an example of such an application-specific variation (extracted from the application in Chapter 50).

Listing 43-6: A Custom Validation Function

```
// function to determine if value is in acceptable range
// for this application
function inRange(inputStr) {
    num = parseInt(inputStr)
    if (num < 1 || num > 586 && num < 596 || num > 599 && num < 700 || num >
728) {
        return false
    }
    return true
}
```

For this application, you need to see if an entry falls within multiple ranges of acceptable numbers. The first statement of the `inRange()` function converts the incoming value to a number (via the `parseInt()` function) so that the value can be compared numerically against maximum and minimum values of several ranges within the database. Following the logic of the previous validation functions, the `if` condition looks for values outside the acceptable range, so it can alert the user and return a `false` value.

The `if` condition is quite a long sequence of operators. As you noticed in the list of operator precedence (Chapter 40), the Boolean AND operator (`&&`) has precedence over the Boolean OR operator (`||`). Therefore, the AND expressions evaluate first, followed by the OR expressions. Parentheses may help you better visualize what's going on in that monster condition:

```
if (num < 1 || (num > 586 && num < 596) || (num > 599 && num < 700) || num > 728)
```

In other words, you exclude four possible ranges from consideration:

- ♦ Values less than 1
- ♦ Values between 586 and 596
- ♦ Values between 599 and 700
- ♦ Values greater than 728

Any value for which any one of these tests is true yields a Boolean `false` from this function. Combining all these tests into a single condition statement eliminates the need to construct an otherwise complex series of nested `if` constructions.

Combining Validation Functions

When you design a page that requests a particular kind of text input from a user, you often need to call more than one data-validation function to handle the entire job. For example, if you merely want to test for a positive integer entry, your validation should test for the presence of any entry as well as the validation as an integer.

After you know the kind of permissible data that your script will use after validation, you're ready to plot the sequence of data validation. Because each page's validation task is different, I supply some guidelines to follow in this planning rather than prescribe a fixed route for all to take.

My preferred sequence is to start with examinations that require less work and increase the intensity of validation detective work with succeeding functions. I borrow this tactic from real life: When a lamp fails to turn on, I look for a pulled plug or a burned-out lightbulb before tearing the lamp's wiring apart to look for a short.

Using the data-validation sequence from the data-entry field (which must be a three-digit number within a specified range) in Chapter 50, I start with the test that requires the least amount of work: Is there an entry at all? After my script is ensured an entry of some kind exists, it next checks whether that entry is "all numbers as requested of the user." If so, the script compares the number against the ranges of numbers in the database.

To make this sequence work together efficiently, I create a master validation function consisting of nested `if...else` statements. Each `if` condition calls one of the generalized data-validation functions. Listing 43-7 shows the master validation function.

Listing 43-7: Master Validation Function

```
// Master value validator routine
function isValid(inputStr) {
    if (isEmpty(inputStr)) {
        alert("Please enter a number into the field before clicking the
button.")
        return false
    } else {
        if (!isNumber(inputStr)) {
            alert("Please make sure entries are numbers only.")
            return false
        } else {
            if (!inRange(inputStr)) {
                var msg = "Sorry, the number you entered is not part of our
database."
                msg += "Try another three-digit number."
                alert(msg)
                return false
            }
        }
    }
    return true
}
```

This function, in turn, is called by the function that controls most of the work in this application. All that the main function wants to know is whether the entered number is valid. The details of validation are handed off to the `isValid()` function and its special-purpose validation testers.

I construct the logic in Listing 43-7 so that if the input value fails to be valid, the `isValid()` function alerts the user of the problem and returns `false`. That means I have to watch my `true`s and `false`s very carefully.

In the first validation test, an empty value is a bad thing; thus, when the `isEmpty()` function returns `true`, the `isValid()` function returns `false` because an empty string is not a valid entry. In the second test, a number value is good so the logic has to flip 180 degrees. The `isValid()` function returns `false` only if the

`isNumber()` function returns `false`. But because `isNumber()` returns `true` when the value is a number, I switch the condition to test for the opposite results of the `isNumber()` function by negating the function name (preceding the function with the Boolean NOT (!) operator). This operator works only with a value that evaluates to a Boolean expression—which the `isNumber()` function always does. The final test for being within the desired range works on the same basis as `isNumber()`, using the Boolean NOT operator to turn the results of the `inRange()` function into the method that works best for this sequence.

Finally, if all validation tests fail to find bad or missing data, the entire `isValid()` function returns `true`. The statement that calls this function can now proceed with processing, ensured that the value entered by the user will work.

There is one additional point worth reinforcing, especially for newcomers. Although all these functions seem to be passing around the same input string as a parameter, notice that any changes made to the value (such as converting it to a string or number) are kept private to each function. These subfunctions never touch the original value in the calling function—they work only with copies of the original value. Therefore, even after the data validation takes place, the original value is in its original form and ready to go.

Date and Time Validation

You can scarcely open a bigger can of cultural worms than when trying to program around the various date and time formats in use around the world. If you have ever looked through the possible settings in your computer's operating system, you can begin to understand the difficulty of this issue.

Trying to write JavaScript that accommodates all of the world's date and time formats for validation is an enormous, if not wasteful, challenge. It's one thing to validate that a text box contains data in the form `xx/xx/xxxx`, but there are also valid value concerns that can get very messy on an international basis. For example, while North America typically uses the `mm/dd/yyyy` format, a large portion of the rest of the world uses `dd/mm/yyyy` (with different delimiter characters, as well). Therefore, how should your validation routine treat the entry `20/03/2002`? Is it incorrect because there are not 20 months in a year; or is it correct as March 20th? To query a user for this kind of information, I suggest you divide the components into individually validated fields (separate text objects for hours and minutes) or make SELECT element entries whose individual values can be assembled at submit time into a hidden date field for processing by the database that needs the date information. (Alternately, you can let your server CGI handle the conversion.)

Despite my encouragement to “divide and conquer” date entries, there may be situations in which you feel it's safe to provide a single text box for date entry (perhaps for a form that is used on a corporate intranet strictly by users in one country). You see some more sophisticated code later in this chapter, but a “quick-and-dirty” solution runs along these lines:

1. Use the entered data (for example, in `mm/dd/yyyy` format) as a value passed to the new `Date()` constructor function.
2. From the newly created date object, extract each of the three components (month, day, and year) into separate numeric values (with the help of `parseInt()`).

3. Compare each of the extracted values against the corresponding date, month, and year values returned by the date object's `getDate()`, `getMonth()`, and `getFullYear()` methods (adjusting for zero-based values of `getMonth()`).
4. If all three pairs of values match, then the entry is apparently valid.

Listing 43-8 puts this action sequence to work. The `validDate()` function receives a reference to the field being checked. A copy of the field's value is made into a date object, and its components are read. If any part of the date conversion or component extraction fails (because of improperly formatted data or unexpected characters), one or more of the variable values becomes `NaN`. This code assumes that the user enters a date in the `mm/dd/yyyy` format, which is the sequence that the `Date` object constructor expects its data. If the user enters `dd/mm/yyyy`, the validation fails for any day beyond the twelfth.

Listing 43-8: Simple Date Validation

```
<HTML>
<HEAD>
<TITLE>Simple Date Validation</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function validDate(fld) {
    var testMo, testDay, testYr, inpMo, inpDay, inpYr, msg
    var inp = fld.value
    status = ""
    // attempt to create date object from input data
    var testDate = new Date(inp)
    // extract pieces from date object
    testMo = testDate.getMonth() + 1
    testDay = testDate.getDate()
    testYr = testDate.getFullYear()
    // extract components of input data
    inpMo = parseInt(inp.substring(0, inp.indexOf("/")), 10)
    inpDay = parseInt(inp.substring((inp.indexOf("/") + 1),
inp.lastIndexOf("/")), 10)
    inpYr = parseInt(inp.substring((inp.lastIndexOf("/") + 1), inp.length), 10)
    // make sure parseInt() succeeded on input components
    if (isNaN(inpMo) || isNaN(inpDay) || isNaN(inpYr)) {
        msg = "There is some problem with your date entry."
    }
    // make sure conversion to date object succeeded
    if (isNaN(testMo) || isNaN(testDay) || isNaN(testYr)) {
        msg = "Couldn't convert your entry to a valid date. Try again."
    }
    // make sure values match
    if (testMo != inpMo || testDay != inpDay || testYr != inpYr) {
        msg = "Check the range of your date value."
    }
}
if (msg) {
    // there's a message, so something failed
    alert(msg)
}
```

<HR>
<FORM NAME="entryForm" onSubmit="return false">
Enter any date (mm/dd/yyyy): <INPUT TYPE="text" NAME="startDate"
    onChange="validDate(this)">
</FORM>
</BODY>
</HTML>

```

Selecting Text Fields for Reentry

During both real-time and batch validations, it is especially helpful to the user if your code — upon discovering an invalid entry — not only brings focus to the subject text field, but also selects the content for the user. By preselecting the entire field, you make it easy for the user to just retype the data into the field for another attempt (or to begin using the left and right arrow keys to move the insertion cursor for editing). The reverse type on the field text also helps bring attention to the field. (Not all operating systems display a special rectangle around a focused text field.)

Form fields have both `focus()` and `select()` methods, which you should invoke for the subject field in that order. IE for Windows, however, exhibits undesirable behavior when trying to focus and select a field immediately after you close an alert dialog box. In most cases, the field does not keep its focus or selection. This is a timing problem, but one that you can cure by processing the focus and select

actions through a `setTimeout()` method. The bottom of the script code of Listing 43-9 demonstrates how to do this.

Method calls to the form field reside in a separate function (called `doSelection()` in this example). Obviously, the methods need a reference to the desired field, so the `doSelection()` function requires access to that reference. You can use a global variable to accomplish this (set the value in the validation function; read it in the `doSelection()` function), but globals are not elegant solutions to passing transient data. Even though the validation function receives a reference to the field, that is an object reference, and the `setTimeout()` function's first parameter cannot be anything but a string value. Therefore, the reference to the text field provides access to names of both the form and field. The names fill in as index values for arrays so that the assembled string (upon being invoked) evaluates to a valid object reference:

```
"doSelection(document.forms[' + fld.form.name + ''].elements[' + fld.name +
'''])"
```

Notice the generous use of built-in `forms` and `elements` object arrays, which allow the form and field names to assemble the reference without resorting to the onerous `eval()` function.

For timing problems such as this one, no additional time is truly needed to let IE recover from whatever ails it. Thus, the time parameter is set to 0 milliseconds. Using the `setTimeout()` portal is enough to make everything work. There is no penalty for using this construction with NN or IE/Mac, even though they don't need it.

An “Industrial-Strength” Validation Solution

I had the privilege of working on a substantial intranet project that included dozens of forms, often with two or three different kinds of forms displayed simultaneously within a frameset. Data-entry accuracy was essential to the validity of the entire application. My task was to devise a data-entry validation strategy that not only ensured accurate entry of data types for the underlying (SQL) database, but also intelligently prompted users who made mistakes in their data entry.

Structure

From the start, the validation routines were to be in a client-side library linked in from an external `.js` file. That would allow all forms to share the validation functions. Because there were multiple forms displayed in a frameset, it would prove too costly in download time and memory requirements to include the `validations.js` file in every frame's document. Therefore, the library was moved to load in with the frameset. The `<SCRIPT SRC="validations.js"></SCRIPT>` tag set went in the Head portion of the framesetting document.

This logical placement presented a small challenge for the workings of the validations because there had to be two-way conversations between a validation function (in the frameset) and a form element (nested in a frame). The mechanism required that a reference to the frame containing the form element be passed as part of the validation routine so that the validation script could make corrections, automatic formatting, and erroneous field selections from the frameset document's script. (In other words, the frameset script needed a path back to the form element making the validation call.)

Dispatch mechanism

From the specification drawn up for the application, it is clear that there are more than two dozen specific types of validations across all the forms. Moreover, multiple programmers work on different forms. It is helpful to standardize the way validations are called, regardless of the validation type (number, string, date, phone number, and so on).

My idea was to create one `validate()` function that contained parameters for the current frame, the current form element, and the type of validation to perform. This would make it clear to anyone reading the code later that an event handler calling `validate()` performed validation, and the details of the code were in the `validations.js` library file.

In `validations.js`, I converted a string name of a validation type into the name of the function that performs the validation in order to make this idea work. As a bridge between the two, I created what I called a *dispatch lookup table* for all the primary validation routines that would be called from the forms. Each entry of the lookup table had a label consisting of the name of the validation and a method that invoked the function. Listing 43-9 shows an excerpt of the entire lookup table creation mechanism.

Listing 43-9: Creating the Dispatch Lookup Table

```
/*
   Begin validation dispatching mechanism
*/
function dispatcher(validationFunc) {
    this.doValidate = validationFunc
}
var dispatchLookup = new Array()
dispatchLookup["isNotEmpty"] = new dispatcher(isNotEmpty)
dispatchLookup["isPositiveInteger"] = new dispatcher(isPositiveInteger)
dispatchLookup["isDollarsOnly8"] = new dispatcher(isDollarsOnly8)
dispatchLookup["isUSState"] = new dispatcher(isUSState)
dispatchLookup["isZip"] = new dispatcher(isZip)
dispatchLookup["isExpandedZip"] = new dispatcher(isExpandedZip)
dispatchLookup["isPhone"] = new dispatcher(isPhone)
dispatchLookup["isConfirmed"] = new dispatcher(isConfirmed)
dispatchLookup["isNY"] = new dispatcher(isNY)
dispatchLookup["isNum16"] = new dispatcher(isNum16)
dispatchLookup["isM90_M20Date"] = new dispatcher(isM90_M20Date)
dispatchLookup["isM70_0Date"] = new dispatcher(isM70_0Date)
dispatchLookup["isM5_P10Date"] = new dispatcher(isM5_P10Date)
dispatchLookup["isDateFormat"] = new dispatcher(isDateFormat)
```

Each entry of the array is assigned a `dispatcher` object, whose custom object constructor assigns a function reference to the object's `doValidate()` method. For these assignment statements to work, their corresponding functions must be defined earlier in the document. You can see some of these functions later in this section.

The link between the form elements and the dispatch lookup table is the `validate()` function, shown in Listing 43-10. A call to `validate()` requires a minimum of three parameters, as shown in the following example:

```
<INPUT TYPE="text" NAME="phone" SIZE="10"
onChange="parent.validate(window, this, 'isPhone')">
```

The first is a reference to the frame containing the document that is calling the function (passed as a reference to the current window). The second parameter is a reference to the form control element itself (using the `this` operator). After that, you see one or more individual validation function names as strings. This last design allows more than one type of validation to take place with each call to `validate()` (for example, in case a field must check for a data type and check that the field is not empty).

Listing 43-10: Main Validation Function

```
// main validation function called by form event handlers
function validate(frame, field, method) {
    gFrame = frame
    gField = window.frames[frame.name].document.forms[0].elements[field.name]
    var args = validate.arguments
    for (i = 2; i < args.length; i++) {
        if (!dispatchLookup[args[i]].doValidate()) {
            return false
        }
    }
    return true
}
```

In the `validate()` function, the frame reference is assigned to a global variable that is declared at the top of the `validations.js` file. Validation functions in this library need this information to build a reference back to a companion field required of some validations (explained later in this section). A second global variable contains a reference to the calling form element. Because the form element reference by itself does not contain information about the frame in which it lives, the script must build a reference out of the information passed as parameters. The reference must work from the framesetting document down to the frame, its form, and form element name. Therefore, I use the `frame` and `field` object references to get their respective names (within the `frames` and `elements` arrays) to assemble the text field's object reference; the resulting value is assigned to the `gField` global variable. I choose to use global variables in this case because passing these two values to numerous nested validation functions could be difficult to track reliably. Instead, the only parameter passed to specific validation functions is the value under test.

Next, the script creates an array of all arguments passed to the `validate()` function. A `for` loop starts with an index value of 2, the third parameter containing the first validation function name. For each one, the named item's `doValidate()` method is called. If the validation fails, this function returns `false`; but if all

validations succeed, then this function returns `true`. Later you see that this function's returned value is the one that allows or disallows a form submission.

Sample validations

Above the dispatching mechanism in the `validations.js` are the validation functions themselves. Many of the named validation functions have supporting utility functions that other named validation functions often use. Because of the eventual large size of this library file (the production version was about 40KB), I organized the functions into two groups: the named functions first, and the utility functions below them (but still before the dispatching mechanism at the bottom of the document).

To demonstrate how some of the more common data types are validated for this application, I show several validation functions and, where necessary, their supporting utility functions. Figure 43-1 shows a sample form that takes advantage of these validations. (You have a chance to try it later in this chapter.) When you are dealing with critical corporate data, you must go to extreme lengths to ensure valid data. And to help users see their mistakes quickly, you need to build some intelligence into validations where possible.

The screenshot shows a Microsoft Internet Explorer window titled "GiantCo Contractor Database - Microsoft Internet Explorer". The browser's address bar shows "Local intranet". The main content area displays a form titled "Contractor Information" with the following fields and controls:

- First Name: CHARLES
- Last Name: ALKAN
- Company: FINGER TWISTERS, INC
- Address 1: 40 AESOP WAY
- Address 2: (empty)
- City: SALTARELLE
- State: LA LOUISIANA
- ZIP: (empty)
- Phone: (empty)
- SSN: (empty)
- Licensed (Y/N/U): (empty)
- No. of Employees: (empty)
- Liability Cov Amt: (empty)
- Coverage Exp. Date: (empty)
- Confirm: (empty)

At the bottom of the form are two buttons: "Save" and "Reset".

Figure 43-1: Sample form for industrial-strength validations

U.S. state name

The design specification for forms that require entry of a U.S. state calls for entry of the state's two-character abbreviation. A companion field to the right displays the entire state name as user feedback verification. The `onChange` event handler not only calls the validation, but it also feeds the focus to the field following the expanded state field so users are less likely to type into it.

Before the validation can even get to the expansion part, it must first validate that the entry is a valid, two-letter abbreviation. Because I need both the abbreviation and the full state name for this validation, I create an array of all the states using each state abbreviation as the index label for each entry. Listing 43-11 shows that array creation.

Listing 43-11: Creating a U.S. States Array

```
// States array
var USStates = new Array(51)
USStates["AL"] = "ALABAMA"
USStates["AK"] = "ALASKA"

```

USStates["SD"] = "SOUTH DAKOTA"
USStates["TN"] = "TENNESSEE"
USStates["TX"] = "TEXAS"
USStates["UT"] = "UTAH"
USStates["VT"] = "VERMONT"
USStates["VA"] = "VIRGINIA"
USStates["WA"] = "WASHINGTON"
USStates["WV"] = "WEST VIRGINIA"
USStates["WI"] = "WISCONSIN"
USStates["WY"] = "WYOMING"

```

The existence of this array comes in handy in determining if the user enters a valid, two-state abbreviation. Listing 43-12 shows the actual `isUSState()` validation function that puts this array to work.

The function's first task is to assign an uppercase version of the entered value to a local variable (`inputStr`), which is the value being analyzed throughout the rest of the function. If the user enters something in the field (`length > 0`) but no entry in the `USStates` array exists for that value, the entry is not a valid state abbreviation. Time to go to work to help out the user.

Listing 43-12: Validation Function for U.S. States

```

// input value is a U.S. state abbreviation; set entered value to all uppercase
// also set companion field (NAME="<xxx>_expand") to full state name
function isUSState() {
    var inputStr = gField.value.toUpperCase()
    if (inputStr.length > 0 && USStates[inputStr] == null) {
        var msg = ""
        var firstChar = inputStr.charAt(0)
        if (firstChar == "A") {
            msg += "\n(Alabama = AL; Alaska = AK; Arizona = AZ; Arkansas = AR)"
        }
        if (firstChar == "D") {
            msg += "\n(Delaware = DE; District of Columbia = DC)"
        }
        if (firstChar == "I") {
            msg += "\n(Idaho = ID; Illinois = IL; Indiana = IN; Iowa = IA)"
        }
        if (firstChar == "M") {
            msg += "\n(Maine = ME; Maryland = MD; Massachusetts = MA; " +
                "Michigan = MI; Minnesota = MN; Mississippi = MS; " +
                "Missouri = MO; Montana = MT)"
        }
        if (firstChar == "N") {
            msg += "\n(Nebraska = NE; Nevada = NV)"
        }
        alert("Check the spelling of the state abbreviation." + msg)
        gField.focus()
        gField.select()
        return false
    }
}

```

```
    }  
    gField.value = inputStr  
    var expandField =  
window.frames[gFrame.name].document.forms[0].elements[gField.name + "_expand"]  
    expandField.value = USStates[inputStr]  
    return true  
}
```

The function assumes that the user tried to enter a valid state abbreviation but either had incorrect source material or momentarily forgot a particular state's abbreviation. Therefore, the function examines the first letter of the entry. If that first letter is any one of the five identified as causing the most difficulty, a legend for all states beginning with that letter is assigned to the `msg` variable (for running on newer browsers only, a `switch` construction is preferred). An alert message displays the generic alert, plus any special legend if one is assigned to the `msg` variable. When the user closes the alert, the field has focus and its text is selected. (This application runs solely on Navigator, so the IE `setTimeout()` workaround isn't needed—but you can add it very easily, especially thanks to the global variable reference for the field.) The function returns `false` at this point.

If, on the other hand, the abbreviation entry is a valid one, the field is handed the uppercase version of the entry. The script then uses the two global variables set in `validate()` to create a reference to the expanded display field (whose name must be the same as the entry field plus `"_expand"`). That expanded display field is then supplied the `USStates` array entry value corresponding to the abbreviation label. All is well with this validation, so it returns `true`.

You can see here that the so-called validation routine is doing far more than simply checking validity of the data. By communicating with the field, converting its contents to uppercase, and talking to another field in the form, a simple call to the validation function yields a lot of mileage.

Date validation

Many of the forms in this application have date fields. In fact, dates are an important part of the data maintained in the database behind the forms. All users of this application are familiar with standard date formats in use in the United States, so I don't have to worry about the possibility of cultural variations in date formats. Even so, I want the date entry to accommodate the common date formats, such as `mmddyyyy`, `mm/dd/yyyy`, and `mm-dd-yyyy` (as well as accommodate two-digit year entries spanning 1930 to 2029).

The plan also calls for going further in helping users enter dates within certain ranges. For example, a field used for a birth date (the listings are for medical professionals) should recommend dates starting no more than 90 years, and no less than 20 years, from the current date. And to keep this application running well into the future, the ranges should be on a sliding scale from the current year, no matter when it might be. Whatever the case, the date range validation is only a recommendation and not a transaction stopper.

Rather than create separate validation functions for each date field, I create a system of reusable validation functions for each date range (several fields on different forms require the same date ranges). Each one of these individual functions calls a single, generic date-validation function that handles the date-range checking. Listing 43-13 shows a few examples of these individual range-checking functions.

Listing 43-13: Date Range Validations

```

// Date Minus 90/Minus 20
function isM90_M20Date() {
    if (gField.value.length == 0) return true
    var thisYear = getTheYear()
    return isDate((thisYear - 90),(thisYear - 20))
}

// Date Minus 70/Minus 0
function isM70_0Date() {
    if (gField.value.length == 0) return true
    var thisYear = getTheYear()
    return isDate((thisYear - 70),(thisYear))
}

// Date Minus 5/Plus 10
function isM5_P10Date() {
    if (gField.value.length == 0) return true
    var thisYear = getTheYear()
    return isDate((thisYear - 5),(thisYear + 10))
}

```

The naming convention I create for the functions includes the two range components relative to the current date. A letter “M” means the range boundary is minus a number of years from the current date; “P” means the range is plus a number of years. If the boundary should be the current year, a zero is used. Therefore, the `isM5_P10Date()` function performs range checking for boundaries between 5 years before and 10 years after the current year.

Before performing any range checking, each function makes sure there is some value to validate. If the field entry is empty, the function returns `true`. This is fine here because dates are not required when the data is unknown.

Next, the functions get the current four-digit year. The code here had to work originally with browsers that did not have the `getFullYear()` method available yet. Therefore, the Y2K fix described in Chapter 36 was built into the application:

```

function getTheYear() {
    var thisYear = (new Date()).getFullYear()
    thisYear = (thisYear < 100)? thisYear + 1900: thisYear
    return thisYear
}

```

The final call from the range validations is to a common `isDate()` function, which handles not only the date range validation but also the validation for valid dates (for example, making sure that September has only 30 days). Listing 43-14 shows this monster-sized function. Because of the length of this function, I interlace commentary within the code listing.

Listing 43-14: Primary Date Validation Function

```
// date field validation (called by other validation functions that specify
minYear/maxYear)
function isDate(minYear,maxYear,minDays,maxDays) {
    var inputStr = gField.value
```

To make it easier to work with dates supplied with delimiters, I first convert hyphen delimiters to slash delimiters. The pre-regular expression `replaceString()` function is the same one described in Chapter 34; it is located in the utility functions part of the `validations.js` file.

```
// convert hyphen delimiters to slashes
while (inputStr.indexOf("-") != -1) {
    inputStr = replaceString(inputStr,"-","/")
}
```

For validating whether the gross format is OK, I check whether zero or two delimiters appear. If the value contains only one delimiter, then the overall formatting is not acceptable. The error alert shows models for acceptable date-entry formats.

```
var delim1 = inputStr.indexOf("/")
var delim2 = inputStr.lastIndexOf("/")
if (delim1 != -1 && delim1 == delim2) {
    // there is only one delimiter in the string
    alert("The date entry is not in an acceptable format.\n\nYou can enter
dates in the following formats: mmdyyy, mm/dd/yyyy, or mm-dd-yyyy. (If the
month or date data is not available, enter '01' in the appropriate
location.)")
    gField.focus()
    gField.select()
    return false
}
```

If there are two delimiters, I tear apart the string into components for month, day, and year. Because two-digit entries can begin with zeros, I make sure the `parseInt()` functions specify base-10 conversions.

```
if (delim1 != -1) {
    // there are delimiters; extract component values
    var mm = parseInt(inputStr.substring(0,delim1),10)
    var dd = parseInt(inputStr.substring(delim1 + 1,delim2),10)
    var yyyy = parseInt(inputStr.substring(delim2 + 1, inputStr.length),10)
```

For no delimiters, I tear apart the string and assume two-digit entries for the month and day and two or four digits for the year.

```
} else {
    // there are no delimiters; extract component values
    var mm = parseInt(inputStr.substring(0,2),10)
    var dd = parseInt(inputStr.substring(2,4),10)
    var yyyy = parseInt(inputStr.substring(4,inputStr.length),10)
}
```

The `parseInt()` functions reveal whether any entry is not a number by returning `NaN`, so I check whether any of the three values is not a number. If so, then an alert signals the formatting problem and supplies acceptable models.

```

    if (isNaN(mm) || isNaN(dd) || isNaN(yyyy)) {
        // there is a non-numeric character in one of the component values
        alert("The date entry is not in an acceptable format.\n\nYou can enter
dates in the following formats: mmddyyyy, mm/dd/yyyy, or mm-dd-yyyy.")
        gField.focus()
        gField.select()
        return false
    }

```

Next, I perform some gross range validation on the month and date to make sure that months are entered from 1 to 12 and dates from 1 to 31. I take care of aligning exact month lengths later.

```

    if (mm < 1 || mm > 12) {
        // month value is not 1 thru 12
        alert("Months must be entered between the range of 01 (January) and 12
(December).")
        gField.focus()
        gField.select()
        return false
    }
    if (dd < 1 || dd > 31) {
        // date value is not 1 thru 31
        alert("Days must be entered between the range of 01 and a maximum of 31
(depending on the month and year).")
        gField.focus()
        gField.select()
        return false
    }

    // validate year, allowing for checks between year ranges
    // passed as parameters from other validation functions

```

Before getting too deep into the year validation, I convert any two-digit year within the specified range to its four-digit equivalent.

```

    if (yyyy < 100) {
        // entered value is two digits, which we allow for 1930-2029
        if (yyyy >= 30) {
            yyyy += 1900
        } else {
            yyyy += 2000
        }
    }

    var today = new Date()

```

I designed this function to work with a pair of year ranges or date ranges (so many days before and/or after today). If the function is passed date ranges, then the first two parameters must be passed as `null`. This first batch of code works with the date ranges (because the `minYear` parameter is `null`).

```

    if (!minYear) {
        // function called with specific day range parameters
        var dateStr = new String(monthDayFormat(mm) + "/" + monthDayFormat(dd) +
            "/" + yyyy)
        var testDate = new Date(dateStr)
        if (testDate.getTime() < (today.getTime() + (minDays * 24 * 60 * 60 *
1000))) {
            alert("The most likely range for this entry begins " + minDays +
                " days from today.")
        }
        if (testDate.getTime() > today.getTime() + (maxDays * 24 * 60 * 60 *
1000)) {
            alert("The most likely range for this entry ends " + maxDays +
                " days from today.")
        }
    }

```

You can also pass hard-wired, four-digit years as parameters. The following branch compares the entered year against the range specified by those passed year values.

```

    } else if (minYear && maxYear) {
        // function called with specific year range parameters
        if (yyyy < minYear || yyyy > maxYear) {
            // entered year is outside of range passed from calling function
            alert("The most likely range for this entry is between the years " +
minYear + " and " + maxYear + ". If your source data indicates a date outside
this range, then enter that date.")
        }
    } else {

```

For year parameters passed as positive or negative year differences, I begin processing by getting the four-digit year for today's date. Then I compare the entered year against the passed range values. If the entry is outside the desired range, an alert reveals the preferred year range within which the entry should fall. But the function does not return any value here because an out-of-range value is not critical for this application.

```

        // default year range (now set to (this year - 100) and (this year +
25))
        var thisYear = today.getYear()
        if (thisYear < 100) {
            thisYear += 1900
        }
        if (yyyy < minYear || yyyy > maxYear) {
            alert("It is unusual for a date entry to be before " + minYear + "
or after " + maxYear + ". Please verify this entry.")
        }
    }

```

One more important validation is to make sure that the entered date is valid for the month and year. Therefore, the various date components are passed to functions to check against month lengths, including the special calculations for the varying length of February. Listing 43-15 shows these functions. The alert messages they display are smart enough to inform the user what the maximum date is for the entered month and year.

```

    if (!checkMonthLength(mm,dd)) {
        gField.focus()
        gField.select()
        return false
    }
    if (mm == 2) {
        if (!checkLeapMonth(mm,dd,yyyy)) {
            gField.focus()
            gField.select()
            return false
        }
    }
}

```

The final task is to reassemble the date components into a format that the database wants for its date storage and stuff it into the form field. If the user enters an all-number or hyphen-delimited date, it is automatically reformatted and displayed as a slash-delimited, four-digit-year date.

```

    // put the Informix-friendly format back into the field
    gField.value = monthDayFormat(mm) + "/" + monthDayFormat(dd) + "/" + yyyy
    return true
}

```

A utility function invoked multiple times in the previous function converts a single-digit month or day number to a string that might have a leading zero:

```

// convert month or day number to string,
// padding with leading zero if needed
function monthDayFormat(val) {
    if (isNaN(val) || val == 0) {
        return "01"
    } else if (val < 10) {
        return "0" + val
    }
    return "" + val
}

```

Listing 43-15: Functions to Check Month Lengths

```

// check the entered month for too high a value
function checkMonthLength(mm,dd) {
    var months = new Array("", "January", "February", "March", "April", "May", "June",
    "July", "August", "September", "October", "November", "December")
    if ((mm == 4 || mm == 6 || mm == 9 || mm == 11) && dd > 30) {
        alert(months[mm] + " has only 30 days.")
        return false
    } else if (dd > 31) {
        alert(months[mm] + " has only 31 days.")
        return false
    }
    return true
}

```

```
// check the entered February date for too high a value
function checkLeapMonth(mm,dd,yyyy) {
  if (yyyy % 4 > 0 && dd > 28) {
    alert("February of " + yyyy + " has only 28 days.")
    return false
  } else if (dd > 29) {
    alert("February of " + yyyy + " has only 29 days.")
    return false
  }
  return true
}
```

This is a rather extensive date-validation routine, but it demonstrates how thorough you must be when a database relies on accurate entries. The more prompting and assistance you can give to users to ferret out problems with invalid entries, the happier those users will be.

Cross-confirmation fields

The final validation type that I cover here is probably not a common request, but it demonstrates how the dispatch mechanism created at the outset expands so easily to accommodate this enhanced client request. The situation is that some fields (mostly dates in this application) are deemed critical pieces of data because this data triggers other processes from the database. As a further check to ensure entry of accurate data, a number of values are set up for entry twice in separate fields — and the fields have to match exactly. In many ways, this mirrors the two passes you are often requested to make when you set a password: enter two copies and let the computer compare them to make sure you typed what you intended to type.

I established a system that places only one burden on the many programmers working on the forms: while you can name the primary field anything you want (to help alignment with database column names, for example), you must name the secondary field the same plus "_xcm" — which stands for *cross-confirm*. Then, pass the `isConfirmed` validation name to the `validate()` function after the date range validation name, as follows:

```
onChange="parent.validate(window, this, 'isM5_P10Date','isConfirmed')"
```

In other words, after the entered value is initially checked against a required date range, the `isConfirmed()` validation function compares the fully vetted, properly formatted date in the current field against its parallel entry.

Listing 43-16 shows the one function in `validations.js` that handles the confirmation in both directions. After assigning a copy of the entry field value to the `inputStr` variable, the function next sets a Boolean flag (`primary`) that lets the rest of the script know if the entry field is the primary or secondary field. If the string "_xcm" is missing from the field name, then the entry field is the primary field.

For the primary field branch, the script assembles the name of the secondary field and compares the content of the secondary field's value against the `inputStr` value. If they are not the same, the user is entering a new value into the primary field, and the script empties the secondary field to force reentry to verify that the user enters the proper data.

For the secondary field entry branch, the script assembles a reference to the primary field by stripping away the final five characters of the secondary field's name. I can use the `lastIndexOf()` string method instead of the longer way involving the string's length; but after experiencing so many platform-specific problems with `lastIndexOf()` in Navigator, I decided to play it safe. Finally, the two values are compared, with an appropriate alert displayed if they don't match.

Listing 43-16: Cross-Confirmation Validation

```
// checks an entry against a parallel, duplicate entry to
// confirm that correct data has been entered
// Parallel field name must be the main field name plus "_xcm"
function isConfirmed() {
    var inputStr = gField.value
    // flag for whether field under test is primary (true) or confirmation field
    var primary = (gField.name.indexOf("_xcm") == -1)
    if (primary) {
        // clear the confirmation field if primary field is changed
        var xcmField =
window.frames[gFrame.name].document.forms[0].elements[gField.name + "_ xcm"]
        var xcmValue = xcmField.value
        if (inputStr != xcmValue) {
            xcmField.value = ""
            return true
        }
    } else {
        var xcmField =
window.frames[gFrame.name].document.forms[0].elements[gField.name.substring(0,(g
Field.name.length-5))]
        var xcmValue = xcmField.value
        if (inputStr != xcmValue) {
            alert("The main and confirmation entry field contents do not match.
Both fields must have EXACTLY the same content to be accepted by the database.")
            gField.focus()
            gField.select()
            return false
        }
    }
    return true
}
```

Last-minute check

Every validation event handler is designed to return `true` if the validation succeeds. This comes in handy for the batch validation that performs one final check of the entries triggered by the form's `onSubmit` event handler. This event handler calls a `checkForm()` function and passes the form control object as a parameter. That parameter helps create a reference to the form element that is passed to each validation function.

Because successful validations return `true`, you can nest consecutive validation tests so that the most nested statement of the construction is `return true` because all validations have succeeded. The form's `onSubmit` event handler is as follows:

```
onSubmit="return checkForm(this)"
```

And the following code fragment is an example of a `checkForm()` function. A separate `isDateFormat()` validation function called here checks whether the field contains an entry in the proper format — meaning that it has likely survived the range checking and format shifting of the real-time validation check.

```
function checkForm(form) {
    if (parent.validate(window, form.birthdate, "isDateFormat")) {
        if (parent.validate(window, form.phone, "isPhone")) {
            if (parent.validate(window, form.name, "isNotEmpty")) {
                return true
            }
        }
    }
    return false
}
```

If any one validation fails, the field is given focus and its content is selected (controlled by the individual validation function). In addition, the `checkForm()` function returns `false`. This, in turn, cancels the form submission.

Try it out

Listing 43-17 is a definition for a frameset that not only loads the validation routines described in this section, but also loads a page with a form that exercises the validations in real-time and batch mode just prior to submission. The form appears earlier in this chapter in Figure 43-1.

Listing 43-17: Frameset for Trying validation.js

```
<HTML>
<HEAD>
<TITLE>GiantCo Contractor Database</TITLE>
<SCRIPT LANGUAGE="JavaScript" SRC="validation.js"></SCRIPT>
<SCRIPT LANGUAGE="JavaScript">
function blank() {
    return "<HTML><BODY BGCOLOR='lightsteelblue'></BODY></HTML>"
}
</SCRIPT>
</HEAD>
<FRAMESET FRAMEBORDER COLS="20%,80%">
    <FRAME NAME="toc" SRC="javascript:parent.blank()">
    <FRAME NAME="entries" SRC="1st43-18.htm">
</FRAMESET>
</HTML>
```

The application scenario for the form is the entry of data into a company's contractor database. Some fields are required, and the date field must be cross-confirmed with a second entry of the same data. If the form passes its final validation prior to submission, the form reloads and you see a readout of the form data that would have been submitted from the previous form had the ACTION been set to a server CGI program URI.

Plan for Data Validation

I devoted this entire chapter to the subject of data validation because it represents the one area of error checking that almost all JavaScript authors should be concerned with. If your scripts (client-side or server-side) perform processing on user entries, you want to prevent script errors at all costs.

44

CHAPTER

Scripting Java Applets and Plug-ins

Netscape was the first to implement the facility enabling JavaScript scripts, Java applets, and plug-ins to communicate with each other under one technology umbrella, called LiveConnect (first implemented in NN3). Microsoft met the challenge and implemented a large part of that technology for IE4/Windows, but of course without using the Netscape-trademarked name for the technology. The name is a convenient way to refer to the capability, so you find it used throughout this chapter applying to both NN and IE browsers that support such facilities. This chapter focuses on the scripting side of LiveConnect: approaching applets and plug-ins from scripts and accessing scripts from Java applets.

Except for the part about talking to scripts from inside a Java applet, I don't assume you have any knowledge of Java programming. The primary goal here is to help you understand how to control applets and plug-ins (including ActiveX controls in IE/Windows) from your scripts. If you're in a position to develop specifications for applets, you also learn what to ask of your Java programmers. But if you are also a Java applet programmer, you learn the necessary skills to get your applets in touch with HTML pages and scripts.

LiveConnect Overview

Before you delve too deeply into the subject, you should be aware that LiveConnect features are not available in all modern browsers, much to the chagrin of many. The following browsers do not support this technology:

- ◆ IE/Macintosh (at least through Version 5)
- ◆ NN4.6 (due to an oversight when the version was released)
- ◆ NN6.0 (work is afoot to include it in later versions)

In This Chapter

Communicating with Java applets from scripts

Accessing scripts and objects from Java applets

Controlling scriptable plug-ins

Such a broad swath of browsers not supporting the feature (especially the IE for Macintosh, which has been factory-installed as the default browser on millions of Macs), makes it difficult to design a public Web application that relies on LiveConnect features. Design your pages accordingly.

The internal mechanisms that allow scripts to communicate with applets and plug-ins are quite different for NN and IE. NN3 and NN4 relied exclusively on the Java virtual machine (JVM) that shipped with most OS platform versions of the browsers. In NN4+, the JVM doesn't load until it is needed, sometimes causing a brief delay in initial execution. For the most part, though, the underlying Java engine is invisible to the scripter (you) and certainly to the visitors of your sites. At most, visitors see statusbar messages about applets loading and running.

IE/Windows, on the other hand, has its own internal architecture for communicating between processes. To Windows, most processes are treated as components that have properties and methods accessible to other components.

Whether you use the technology to communicate with a Java applet or an ActiveX control, the advantage to you as an author is that LiveConnect extends the document object model to include objects and data types that are not a part of the HTML world. HTML, for instance, does not have a form element that displays real-time stock ticker data; nor does HTML have the capability to treat a sound file like anything more than a URL to be handed off to a helper application. With LiveConnect, however, your scripts can treat the applet that displays the stock ticker as an object whose properties and methods can be modified after the applet loads; scripts can also tell the sound when to play or pause by controlling the plug-in that manages the incoming sound file.

Why Control Java Applets?

A question I often hear from experienced Java programmers is, "Why bother controlling an applet via a script when you can build all the interactivity you want into the applet itself?" This question is valid if you come from the Java world, but it takes a viewpoint from the HTML and scripting world to fully answer it.

Java applets exist in their own private rectangles, remaining largely oblivious to the HTML surroundings on the page. Applet designers who don't have extensive Web page experience tend to regard their applets as the center of the universe rather than as components of HTML pages.

As a scripter, on the other hand, you may want to use those applets as powerful components to spiff up the overall presentation. Using applets as prewritten objects enables you to make simple changes to the HTML pages — including the geographic layout of elements and images — at the last minute, without having to rewrite and recompile Java program code. If you want to update the look with an entirely new graphical navigation or control bar, you can do it directly via HTML and scripting.

When it comes to designing or selecting applets for inclusion into my scripted page, I prefer using applet interfaces that confine themselves to data display, putting any control of the data into the hands of the script, rather than using onscreen buttons in the applet rectangle. I believe this setup enables much greater last-minute flexibility in the page design — not to mention consistency with HTML form element interfaces — than putting everything inside the applet rectangle.

A Little Java

If you plan to look at a Java applet's scripted capabilities, you can't escape having to know a little about Java applets and some terminology. The discussion goes more deeply into object orientation than you have seen with JavaScript, but I'll try to be gentle.

Java building blocks classes

One part of Java that closely resembles JavaScript is that Java programming deals with objects, much the way JavaScript deals with a page's objects. Java objects, however, are not the familiar HTML objects but rather more basic building blocks, such as tools that draw to the screen and data streams. But both languages also have some non-HTML kinds of objects in common: strings, arrays, numbers, and so on.

Every Java object is known as a class — a term from the object-orientation world. When you use a Java compiler to generate an applet, that applet is also a class, which happens to incorporate many Java classes, such as strings, image areas, font objects, and the like. The applet file you see on the disk is called a class file, and its file extension is `.class`. This file is the one you specify for the `CODE` attribute of an `<APPLET>` tag.

Java methods

Most JavaScript objects have methods attached to them that define what actions the objects are capable of performing. A string object, for instance, has the `toUpperCase()` method that converts the string to all uppercase letters. Java classes also have methods. Many methods are predefined in the base Java classes embedded inside the virtual machine. But inside a Java applet, the author can write methods that either override the base method or deal exclusively with a new class created in the program. These methods are, in a way, like the functions you write in JavaScript for a page.

Not all methods, however, are created the same. Java lets authors determine how visible a method is to outsiders. The types of methods that you, as a scripter, are interested in are the ones declared as public methods. You can access such methods from JavaScript via a syntax that falls very much in line with what you already know. For example, a common public method in applets stops an applet's main process. Such a Java method may look such as this:

```
public void stop() {
    if(thread != null) {
        thread.stop();
        thread = null;
    }
}
```

The `void` keyword simply means that this method does not return any values (compilers need to know this stuff). Assuming that you have one applet loaded in your page, the JavaScript call to this applet method is

```
document.applets[0].stop()
```

Listing 44-1 shows how all this works with the `<APPLET>` tag for a scriptable digital clock applet example. The script includes calls to two of the applet's methods: to stop and to start the clock.

Listing 44-1: Stopping and Starting an Applet

```
<HTML>
<HEAD>
<TITLE>A Script That Could Stop a Clock</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function pauseClock() {
    document.clock1.stop()
}
function restartClock() {
    document.clock1.start()
}
</SCRIPT>
<BODY>
<H1>Simple control over an applet</H1>
<HR>
<APPLET CODE="ScriptableClock.class" NAME="clock1" WIDTH=500 HEIGHT=45>
<PARAM NAME=bgColor VALUE="Green">
<PARAM NAME=fgColor VALUE="Blue">
</APPLET>
<P>
<FORM NAME="widgets1">
<INPUT TYPE="button" VALUE="Pause Clock" onClick="pauseClock()">
<INPUT TYPE="button" VALUE="Restart Clock" onClick="restartClock()">
</FORM>
</BODY>
</HTML>
```

The syntax for accessing the method (in the two functions) is just like JavaScript in that the references to the applet's methods include the applet object (`clock1` in the example), which is contained by the `document` object.

Java applet “properties”

The Java equivalents of JavaScript object properties are called *public instance variables*. These variables are akin to JavaScript global variables. If you have access to some Java source code, you can recognize a public instance variable by its public keyword:

```
public String fontName
```

Java authors must specify a variable's data type when declaring any variable. That's why the `String` data type appears in the preceding example.

Your scripts can access these variables with the same kind of syntax that you use to access JavaScript object properties. If the `fontName` variable in `ScriptableClock.class` had been defined as a public variable (it is not), you could access or set its value directly, as shown in the following example.

```
var theFont = document.applets[0].fontName
document.applets[0].fontName = "Courier"
```

Accessing Java fields

In a bit of confusing lingo, public variables and methods are often referred to as *fields*. These elements are not the kind of text entry fields that you see on the screen; rather, they're like slots (another term used in Java) where you can slip in your requests and data. Remember these terms, because they may appear from time to time in error messages as you begin scripting applets.

Scripting Applets in Real Life

Because the purpose of scripting an applet is to gain access to the inner sanctum of a compiled program, the program should be designed to handle such rummaging around by scripters. If you can't acquire a copy of the source code or don't have any other documentation about the scriptable parts of the applet, you may have a difficult time knowing what to script and how to do it.

Although the applet's methods are reflected as properties in an applet object, writing a `for . . . in` loop to examine these methods tells you perhaps too much. Figure 44-1 shows a partial listing of such an examination of the `ScriptableClock` applet. This applet has only public methods (no variables), but the full listing shows the dozens of fields accessible in the applet. What you probably won't recognize, unless you have programmed in Java, is that within the listing are dozens of fields belonging to the Java classes that automatically become a part of the applet during compilation. From this listing, you have no way to distinguish the fields defined or overridden in the applet code from the base Java fields.

fieldName	fieldValue
	[JavaMethod ScriptableClock.]
getInfo	[JavaMethod ScriptableClock.getInfo]
setColor	[JavaMethod ScriptableClock.setColor]
setFont	[JavaMethod ScriptableClock.setFont]
setTimeZone	[JavaMethod ScriptableClock.setTimeZone]
paint	[JavaMethod ScriptableClock.paint]
run	[JavaMethod ScriptableClock.run]
stop	[JavaMethod ScriptableClock.stop]
start	[JavaMethod ScriptableClock.start]
init	[JavaMethod ScriptableClock.init]
destroy	[JavaMethod ScriptableClock.destroy]
play	[JavaMethod ScriptableClock.play]
getParameterInfo	[JavaMethod ScriptableClock.getParameterInfo]
getAppletInfo	[JavaMethod ScriptableClock.getAppletInfo]
getAudioClip	[JavaMethod ScriptableClock.getAudioClip]

Figure 44-1: Partial listing of fields from `ScriptableClock`

Getting to scriptable methods

If you write your own applets or are fortunate enough to have the source code for an existing applet, the safest way to modify the applet variable settings or the running processes is through applet methods. Although setting a public variable value may enable you to make a desired change, you don't know how that change may impact other parts of the applet. An applet designed for scriptability should

have a number of methods defined that enable you to make scripted changes to variable values.

To view a sample of an applet designed for scriptability, open the Java source code file for Listing 44-2 from the CD-ROM. A portion of that program listing is shown in the following example.

Listing 44-2: Partial Listing for ScriptableClock.java

```

/*
   Begin public methods for getting
   and setting data via LiveConnect
*/
public void setTimeZone(String zone) {
    stop();
    timeZone = (zone.startsWith("GMT")) ? true : false;
    start();
}

public void setFont(String newFont, String newStyle, String newSize) {
    stop();
    if (newFont != null && newFont != "")
        fontName = newFont;
    if (newStyle != null && newStyle != "")
        setFontStyle(newStyle);
    if (newSize != null && newSize != "")
        setFontSize(newSize);
    displayFont = new Font(fontName, fontStyle, fontSize);
    start();
}

public void setColor(String newbgColor, String newfgColor) {
    stop();
    bgColor = parseColor(newbgColor);
    fgColor = parseColor(newfgColor);
    start();
}

public String getInfo() {
    String result = "Info about ScriptableClock.class\r\n";
    result += "Version/Date: 1.0d1/2 May 1996\r\n";
    result += "Author: Danny Goodman (dannyg@dannyg.com)\r\n";
    result += "Public Variables:\r\n";
    result += "    (None)\r\n\r\n";
    result += "Public Methods:\r\n";
    result += "    setTimeZone(\"GMT\" | \"Locale\")\r\n";
    result += "    setFont(\"fontName\", \"Plain\" | \"Bold\" | \"Italic\",
    \"fontSize\")\r\n";
    result += "    setColor(\"bgColorName\", \"fgColorName\")\r\n";
    result += "    colors: Black, White, Red, Green, Blue, Yellow\r\n";
    return result;
}
/*
   End public methods for scripted access.
*/

```

The methods shown in Listing 44-2 are defined specifically for scripted access. In this case, they safely stop the applet thread before changing any values. The last method is one I recommend to applet authors. The method returns a small bit of documentation containing information about the kind of methods that the applet likes to have scripted and what you can have as the passed parameter values.

Now that you see the amount of scriptable information in this applet, look at Listing 44-3, which takes advantage of that scriptability by providing several HTML form elements as user controls for the clock. The results are shown in Figure 44-2.

Listing 44-3: A More Fully Scripted Clock

```
<HTML>
<HEAD>
<TITLE>Clock with Lots o' Widgets</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">

function setTimeZone(popup) {
    var choice = popup.options[popup.selectedIndex].value
    document.clock2.setTimeZone(choice)
}

function setColor(form) {
    var bg =
form.backgroundColor.options[form.backgroundColor.selectedIndex].value
    var fg =
form.foregroundColor.options[form.foregroundColor.selectedIndex].value
    document.clock2.setColor(bg, fg)
}

function setFont(form) {
    var fontName = form.theFont.options[form.theFont.selectedIndex].value
    var fontStyle = form.theStyle.options[form.theStyle.selectedIndex].value
    var fontSize = form.theSize.options[form.theSize.selectedIndex].value
    document.clock2.setFont(fontName, fontStyle, fontSize)
}

function getAppletInfo(form) {
    form.details.value = document.clock2.getInfo()
}

Very little of the code here controls the applet — only the handful of functions near the top. The rest of the code makes up the HTML user interface for the form element controls. After you open this document from the CD-ROM, be sure to click the Applet Info button to see the methods that you can script and the way that the parameter values from the JavaScript side match up with the parameters on the Java method side.

Figure 44-2: Scripting more of the ScriptableClock applet

Applet limitations

Because of concerns about security breaches via LiveConnect, Netscape clamps down on some powers that would be nice to have via a scripted applet. The most noticeable barrier is the one that prevents applets from accessing the network under scripted control. Therefore, even though a Java applet has no difficulty reading or writing text files from the server, such capabilities — even if built into an applet of your own design — won't be carried out if triggered by a JavaScript call to the applet.

Some clever hacks used to be posted on the Web, but they were rather cumbersome to implement and may no longer work on more modern browsers. You can also program the Java applet to fetch a text file after it starts up and then script the access of that value from JavaScript (as described in the following section). Signed scripts (Chapter 46) and applets can break through these security barriers after the user has given explicit permission to do so.

Faceless applets

Until LiveConnect came along, Java applets were generally written to show off data and graphics — to play a big role in the presentation on the page. But if you prefer to let an applet do the heavy algorithmic lifting for your pages while the HTML form elements and images (or Dynamic HTML facilities of newer browsers) do the user interface, you essentially need what I call a *faceless applet*.

The method for embedding a faceless applet into your page is the same as embedding any applet: Use the `<APPLET>` tag. But specify only 1 pixel for both the `HEIGHT` and `WIDTH` attributes (0 has strange side effects). This setting creates a dot on the screen, which, depending on your page's background color, may be completely invisible to page visitors. Place it at the bottom of the page, if you like.

To show how nicely this method can work, Listing 44-4 provides the Java source code for a simple applet that retrieves a specific text file and stores the results in a Java variable available for fetching by the JavaScript shown in Listing 44-5. The HTML even automates the loading process by triggering the retrieval of the Java applet's data from an `onLoad` event handler.

Listing 44-4: Java Applet Source Code

```
import java.net.*;
import java.io.*;

public class FileReader extends java.applet.Applet implements Runnable {

    Thread thread;
    URL url;
    String output;
    String fileName = "Bill of rights.txt";

    public void getFile(String fileName) throws IOException {
        String result, line;
        InputStream connection;
        DataInputStream dataStream;
        StringBuffer buffer = new StringBuffer();

        try {
            url = new URL(getDocumentBase(), fileName);
        }
        catch (MalformedURLException e) {
            output = "AppletError " + e;
        }

        try {
            connection = url.openStream();
            dataStream = new DataInputStream(new
BufferedInputStream(connection));

            while ((line = dataStream.readLine()) != null) {
                buffer.append(line + "\n");
            }
            result = buffer.toString();
        }
    }
}
```

```
        catch (IOException e) {
            result = "AppletError: " + e;
        }
        output = result;
    }

    public String fetchText() {
        return output;
    }

    public void init() {
    }

    public void start() {
        if (thread == null) {
            thread = new Thread(this);
            thread.start();
        }
    }

    public void stop() {
        if (thread != null) {
            thread.stop();
            thread = null;
        }
    }

    public void run(){
        try {
            getFile(fileName);
        }
        catch (IOException e) {
            output = "AppletError: " + e;
        }
    }
}
```

All the work of actually retrieving the file is performed in the `getFile()` method (which runs immediately after the applet loads). Notice that the name of the file to be retrieved, `Bill of Rights.txt`, is stored as a variable near the top of the code, making it easy to change for a recompilation, if necessary. You can also modify the applet to accept the file name as an applet parameter, specified in the HTML code. Meanwhile, the only hook that JavaScript needs is the one public method called `fetchText()`, which merely returns the value of the output variable, which in turn holds the file's contents.

This Java source code must be compiled into a Java class file (already compiled and included on the CD-ROM as `FileReader.class`) and placed in the same directory as the HTML file that loads this applet. Also, no explicit pathname for the text file is supplied in the source code, so the text file is assumed to be in the same directory as the applet.

Listing 44-5: HTML Asking Applet to Read Text File

```

<HTML>
<HEAD>
<TITLE>Letting an Applet Do The Work</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
function getFile(form) {
    var output = document.readerApplet.fetchText()
    form.fileOutput.value = output
}
function autoFetch() {
    var output = document.readerApplet.fetchText()
    if (output != null) {
        document.forms[0].fileOutput.value = output
        return
    }
    var t = setTimeout("autoFetch()",1000)
}
</SCRIPT>
</HEAD>
<BODY onLoad="autoFetch()">

<H1>Text from a text file...</H1>
<FORM NAME="reader">
<INPUT TYPE="button" VALUE="Get File" onClick="getFile(this.form)">
<P>
<TEXTAREA NAME="fileOutput" ROWS=10 COLS=60 WRAP="hard"></TEXTAREA>
<P>
<INPUT TYPE="Reset" VALUE="Clear">
</FORM>
<APPLET CODE="FileReader.class" NAME="readerApplet" WIDTH=1 HEIGHT=1>
</APPLET>
</BODY>
</HTML>

```

Because an applet is usually the last detail to finish loading in a document, you can't use an applet to generate the page immediately. At best, an HTML document can display a pleasant welcome screen while the applet finishes loading itself and running whatever it does to prepare data for the page's form elements. In IE4+, the page can then be dynamically constructed out of the retrieved data; for NN4, you can create a new layer object, and use `document.write()` to install content into that layer. Notice in Listing 44-5 that the `onLoad` event handler calls a function that checks whether the applet has supplied the requested data. If not, then the same function is called repeatedly in a timer loop until the data is ready and the textarea can be set. The `<APPLET>` tag is located at the bottom of the Body, set to 1 pixel square—invisible to the user. No user interface exists for this applet, so you have no need to clutter up the page with any placeholder or bumper sticker.

Figure 44-3 shows the page generated by the HTML and applet working together. The Get File button is merely a manual demonstration of calling the same applet method that the `onLoad` event handler calls.

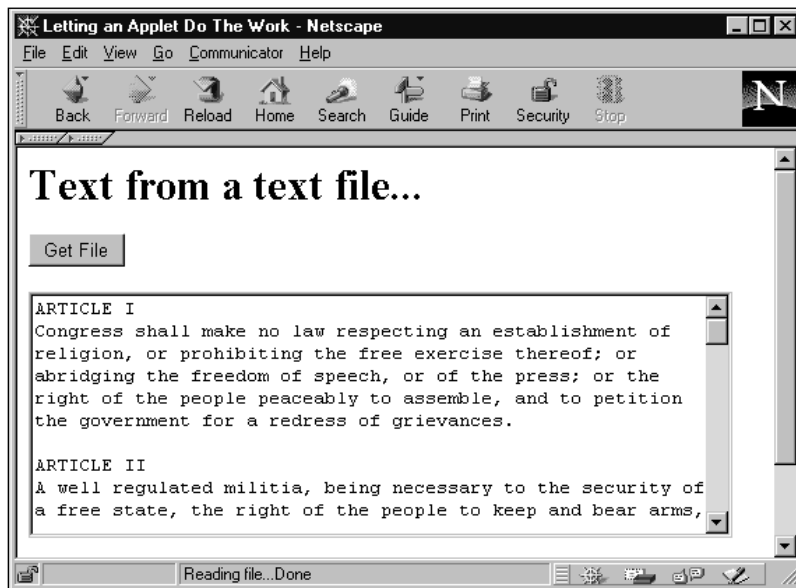

Figure 44-3: The page with text retrieved from a server file

A faceless applet may be one way for Web authors to hide what may otherwise be JavaScript code that is open to any visitor's view. For example, if you want to deliver a small data collection lookup with a document, but don't want the array of data to be visible in the JavaScript code, you can create the array and lookup functionality inside a faceless applet. Then use form controls and JavaScript to act as query entry and output display devices (or dynamically generate a table in IE4+). Because the parameter values passed between JavaScript and Java applets must be string, numeric, or Boolean values, you won't be able to pass arrays without performing some amount of conversion either within the applet or the JavaScript code (JavaScript's `string.split()` and `array.join()` methods help a great deal here).

Data type conversions

The example in this chapter does not pass any parameters to the applet's methods, but you are free to do so. You need to pay attention to the way in which values are converted to Java data types. JavaScript strings and Boolean values are converted to Java `String` and `Boolean` objects. All JavaScript numbers, regardless of their subtype (that is, integer or floating-point number), are converted to `Float` objects. Therefore, if a method must accept a numeric parameter from a script, the parameter variable in the Java method must be defined as a `Float` type.

The distinction between JavaScript string values and string objects can impact data being passed to an applet. If an applet method requires a string object as a parameter, you may have to explicitly convert a JavaScript string value (for example, a string from a text field) to a string object via the new `String()` constructor (Chapter 34).

You can also pass references to objects, such as form control elements. Such objects get wrapped with a `JSObject` type (see discussion about this class later in the chapter). Therefore, parameter variables must be established as type `JSObject` (and the `netscape.javascript.JSObject` class must be imported into the applet).

Applet-to-Script Communication

The flip side of scripted applet control is having an applet control script and HTML content in the page. Before you undertake this avenue in page design, you must bear in mind that any calls made from the applet to the page are hard-wired for the specific scripts and HTML elements in the page. If this level of tight integration and dependence suits the application, the link up will be successful.

Note

The discussion of applet-to-script communication assumes you have experience writing Java applets. I use Java jargon quite freely in this discussion.

What your applet needs

NN3 and NN4 come with a zipped set of special class files tailored for use in LiveConnect. In NN3, the file is named `java_30` or `java_301`, the latter one being the latest version; in NN4, the file is named `java40.jar`. For NN6, the class files are located in an archive called `jaws.jar` (Windows) or `MRJPlugin.jar` (Mac). Use the file search facility of the OS to locate the relevant file on your system. Microsoft versions of these class files are also included in IE4+, buried in one of the large `.zip` files in the `Windows\Java\Packages` directory (the files you need are in one of the multi-megabyte `.zip` files, whose gibberish names change from version to version — open each with an unzip utility and look for the two packages mentioned next). The browser must see these class files (and have both Java and JavaScript enabled in the preferences screens) for LiveConnect to work.

These zipped class library files contain two vital classes in a `netscape` package (yes, even in IE):

```
netscape.javascript.JSObject
netscape.javascript.JSException
```

Both classes must be imported to your applet via the Java `import` compiler directive:

```
import netscape.javascript.*;
```

When the applet runs, the LiveConnect-aware browser knows how to find the two classes, so that the user doesn't have to do anything special as long as the supporting files are in their default locations.

Perhaps the biggest problem applet authors have with LiveConnect is importing these class libraries for applet compilation. Your Java compiler must be able to see

these class libraries for compilation to be successful. The prescribed method is to include the path to the zipped class file (either the Netscape `.jar` archive or Microsoft `.zip` file) in the class path for the compiler.

Problems frequently occur when the Java compiler you use (perhaps inside an integrated development environment, such as Cafe) doesn't recognize either of the Netscape files as a legitimate zipped class file. You can make your compilation life simpler if you extract the `netscape` package from the `.jar` or `.zip` file, and place it in the same directory in which your compiler looks for the basic Java classes. For example, although the precise details may change in newer versions, Cafe stores the default Java class files inside zipped collections whose class paths (in Windows) are

```
C:\CAFE\BIN\..\JAVA\LIB\CLASSES.ZIP
C:\CAFE\BIN\..\JAVA\LIB\SYMCLASS.ZIP
```

These two class paths are inserted into new projects by default. Extract the two `netscape.java` class files and store them in the same LIB directory as `CLASSES.ZIP` and `SYMCLASS.ZIP`. In other words, in the LIB directory is a directory named `netscape`; inside the `netscape` directory is another directory named `javascript`; inside the `javascript` directory are the `JSObject.class` and `JSEException.class` files. Then I add the following class path to the project's class path setting:

```
C:\CAFE\BIN\..\JAVA\LIB\
```

This path instructs Cafe to start looking for the `netscape` package (which contains the `javascript` package, which, in turn, contains the class files) in that directory.

Depending on the unzipping utility and operating system you use, you may have to force the utility to recognize `.jar` files as zip archive files. If necessary, instruct the utility's file open dialog box to locate all file types in the directory. Both files will open as zipped archives. Sort the long list of files by name. Then select and extract only the two class files into the same directory as your compiler's Java class files. The utility should take care of creating the package directories for you.

What your HTML needs

As a security precaution, an `<APPLET>` tag requires one extra attribute to give the applet permission to access the HTML and scripting inside the document. That attribute is the single word `MAYSCRIPT`, and it can go anywhere inside the `<APPLET>` tag, as follows:

```
<APPLET CODE="myApplet.class" HEIGHT="200" WIDTH="300" MAYSCRIPT>
```

Permission is not required for JavaScript to access an applet's methods or properties, but if the applet initiates contact with the page, this attribute is required.

About JSObject class

The portal between the applet and the HTML page that contains it is the `netscape.java` `JSObject` class. This object's methods let the applet contact document objects and invoke JavaScript statements. Table 44-1 shows the object's methods and one static method.

Table 44-1 **JSObject Class Methods**

<i>Method</i>	<i>Description</i>
<code>call(String functionName, Object args[])</code>	Invokes JavaScript function, argument(s) passed as an array
<code>eval(String expression)</code>	Invokes a JavaScript statement
<code>getMember(String elementName)</code>	Retrieves a named object belonging to a container
<code>getSlot(Int index)</code>	Retrieves indexed object belonging to a container
<code>getWindow(Applet applet)</code>	Static method retrieves applet's containing window
<code>removeMember(String elementName)</code>	Removes a named object belonging to a container
<code>setMember(String elementName, Object value)</code>	Sets value of a named object belonging to a container
<code>setSlot(int index, Object value)</code>	Sets value of an indexed object belonging to a container
<code>toString()</code>	Returns string version of JSObject

Just as the window object is the top of the document object hierarchy for JavaScript references, the window object is the gateway between the applet code and the scripts and document objects. To open that gateway, use the `JSObject.getWindow()` method to retrieve a reference to the document window. Assign that object to a variable that you can use throughout your applet code. The following code fragment shows the start of an applet that assigns the window reference to a variable named `mainwin`:

```
import netscape.javascript.*;

public class myClass extends java.applet.Applet {
    private JSObject mainwin;

    public void init() {
        mainwin = JSObject.getWindow(this);
    }
}
```

If your applet will be making frequent trips to a particular object, you may want to create a variable holding a reference to that object. To accomplish this, the applet needs to make progressively deeper calls into the document object hierarchy with the `getMember()` method. For example, the following sequence assumes `mainwin` is a reference to the applet's document window. Eventually the statements set a form's field object to a variable for use elsewhere in the applet:

```
JSObject doc = (JSObject) mainwin.getMember("document");
JSObject form = (JSObject) doc.getMember("entryForm");
JSObject phonefld = (JSObject) form.getMember("phone");
```

Another option is to use the Java `eval()` method to execute an expression from the point of view of any object. For example, the following statement gets the same field object from the preceding fragment:

```
JSObject phonefld = mainwin.eval("document.entryForm.phone");
```

As soon as you have a reference to an object, you can access its properties via the `getMember()` method, as shown in the following example, which reads the `value` property of the text box, and casts the value into a Java `String` object:

```
String phoneNum = (String) phonefld.getMember("value");
```

Two `JSObject` class methods let your applet execute arbitrary JavaScript expressions and invoke object methods: the `eval()` and `call()` methods. Use these methods with any `JSObject`. If a value is to be returned from the executed statement, you must cast the result into the desired object type. The parameter for the `eval()` method is a string of the expression to be evaluated by JavaScript. Scope of the expression depends on the object attached to the `eval()` method. If you use the `window` object, the expression would exist as if it were a statement in the document script (not defined inside a function).

Using the `call()` method is convenient for invoking JavaScript functions in the document, although it requires a little more preparation. The first parameter is a string of the function name. The second parameter is an array of arguments for the function. Parameters can be of mixed data types, in which case the array would be of type `Object`. If you don't need to pass a parameter to the function call, you can define an array of a single empty string value (for example, `String arg[] = {""}`) and pass that array as the second parameter.

Data type conversions

The strongly typed Java language is a mismatch for loosely typed JavaScript. As a result, with the exception of Boolean and string objects (which are converted to their respective JavaScript objects), you should be aware of the way LiveConnect adapts data types to JavaScript.

Any Java object that contains numeric data is converted to a JavaScript number value. Because JavaScript numbers are IEEE doubles, they can accommodate just about everything Java can throw its way.

If the applet extracts an object from the document and then passes that `JSObject` type back to JavaScript, that passed object is converted to its original JavaScript object type. But objects of other classes are passed as their native objects wrapped in JavaScript "clothing." JavaScript can access the applet object's methods and properties as if the object were a JavaScript object. Finally, Java arrays are converted to the same kind of JavaScript array created via the `new Array()` constructor. Elements can be accessed by integer index values (not named index values). All other JavaScript array properties and methods apply to this object as well.

Example applet-to-script application

To demonstrate several techniques for communicating from an applet to both JavaScript scripts and document objects, I present an applet that displays two simple

buttons (see Figure 44-4). One button generates a new window, spawned from the main window, filling the window with dynamically generated content from the applet. The second button communicates from the applet to that second window by invoking a JavaScript function in the document. One last part of the demonstration shows the applet changing the value of a text box when the applet starts up.

Figure 44-4: The applet displays two buttons seamlessly on the page.

Listing 44-6 shows the source code for the Java applet. For backward compatibility, it uses the JDK 1.02 event-handling model.

Because the applet generates two buttons, the code begins by importing the AWT interface builder classes. I also import the `netscape.javascript` package to get the `JSObject` class. The name of this sample class is `JtoJSDemo`. I declare four global variables: two for the windows, two for the applet button objects.

Listing 44-6: Java Applet Source Code

```
import java.awt.*;
import netscape.javascript.*;

public class JtoJSDemo extends java.applet.Applet {
    private JSObject mainwin, subwin;
    private Button newWinButton, toggleButton;
    void doNewWindow() {
        subwin = (JSObject)
mainwin.eval("window.open('', 'fromApplet', 'HEIGHT=200,WIDTH=200')");
        subwin.eval("<HTML><BODY BGCOLOR=white>Howdy from the
applet!</BODY></HTML>");
        subwin.eval("document.close()");
    }
}
```

The applet's `init()` method establishes the user interface elements for this simple applet. A white background is matched in the HTML with a white document background color, making the applet appear to blend in with the page. I use this opportunity to set the `mainwin` variable to the browser window that contains the applet.

```
public void init() {
    setBackground(Color.white);
    newWinButton = new Button("New Browser Window");
    toggleButton = new Button("Toggle SubWindow Color");
    this.add(newWinButton);
    this.add(toggleButton);
    mainwin = JSObject.getWindow(this);
}
```

As soon as the applet starts, it changes the `value` property of a text box in the HTML form. Because this is a one-time access to the field, I elected to use the `eval()` method from the point of view of the main window, rather than build successive object references through the object hierarchy with the `getMember()` method.

```
public void start() {
    mainwin.eval("document.indicator.running.value = 'Yes'");
}
```

Event handling is quite simple in this application. A click of the first button invokes `doNewWindow()`; a click of the second invokes `toggleColor()`. Both methods are defined later in the applet.

```
public boolean action(Event evt, Object arg) {
    if (evt.target instanceof Button) {
        if (evt.target == newWinButton) {
            doNewWindow();
        } else if (evt.target == toggleButton) {
            toggleColor();
        }
    }
    return true;
}
```

One of the applet's buttons calls the `doNewWindow()` method defined here. I use the `eval()` method to invoke the JavaScript `window.open()` method. The string parameter of the `eval()` method is exactly like the statement that appears in the page's JavaScript to open a new window. The `window.open()` method returns a reference to that subwindow, so that the statement here captures the returned value, casting it as a `JSObject` type for the `subwin` variable. That `subwin` variable can then be used as a reference for another `eval()` method that writes to that second window. Notice that the object to the left of the `eval()` method governs the recipient of the `eval()` method's expression. The same is true for closing the writing stream to the subwindow.

Unfortunately, the IE4+ implementation of `JSObject` does not provide a suitable reference to the external window after it is created. Therefore, the window does not receive its content or respond to color changes in this example. Due to other anomalies with subwindows, I advise against using LiveConnect powers with multiple windows in IE4+.

The second button in the applet calls the `toggleColor()` method. In the HTML document, a JavaScript function named `toggleSubWindowColor()` takes a window object reference as an argument. Therefore, I first assemble a one-element array of type `JSObject` consisting of the `subwin` object. That array is the second parameter of the `call()` method, following a string version of the JavaScript function name being called.

```
void toggleColor() {
    if (subwin != null) {
        JSObject arg[] = {subwin};
        mainwin.call("toggleSubWindowColor", arg);
    }
}
```

Now onto the HTML that loads the above applet class and is the recipient of its calls. The document is shown in Listing 44-7. One function is called by the applet. A text box in the form is initially set to “No” but gets changed to “Yes” by the applet after it has finished its initialization. The only other item of note is that the `<APPLET>` tag includes a `MAYSCRIPT` attribute to allow the applet to communicate with the page.

Listing 44-7: HTML Document Called by Applet

```
<HTML>
<HEAD><TITLE>Java-to-JavaScript Demo</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function toggleSubWindowColor(wind) {
    if (wind.closed) {
        alert("The subwindow is closed. Can't change it's color.")
    } else {
        wind.document.bgColor = (wind.document.bgColor == "#ffffff") ? "red" :
"white"
    }
}
</SCRIPT>
</HEAD>

<BODY BGCOLOR="#FFFFFF">
<B>Here's the applet:</B><BR>
```

```
<APPLET CODE="JtoJSDemo.class" NAME="demoApplet" HEIGHT=150 WIDTH=200 MAYSCRIPT>
</APPLET>

<FORM NAME="indicator">
Is the applet running yet?<INPUT TYPE="text" NAME="running" SIZE="4" VALUE="No">
</FORM>
</BODY>
</HTML>
```

Scripting Plug-ins

Controlling a plug-in (or Windows ActiveX control in IE) from JavaScript is much like controlling a Java applet. But you have more browser-specific concerns to worry about, even at the HTML level. Not all plug-ins are scriptable, of course, nor do all browsers permit such scripting, as described at the start of this chapter. Yet even when you have found the right combination of browser version(s) and plug-in(s), you must also learn what the properties and/or methods of the plug-in are so that your scripts can control them. For common plug-in duties, such as playing audio, the likelihood that all users will have the same audio playback plug-in installed in a particular browser brand and operating system is perhaps too small to entrust your programming to a single plug-in. If, on the other hand, you are using a plug-in that works only with a special data type, then your page need check only that the plug-in is installed (and that it is the desired minimum version).

In this section of the chapter, you'll begin to understand the HTML issues and then examine two separate audio playback examples. One example lets users change tunes being played back; the other arrives with five sounds, each of which is controlled by a different onscreen interface element. Both of these audio playback examples employ a library that has been designed to provide basic audio playback interfaces to the three most popular scriptable audio playback plug-ins:

- ♦ Windows Media Player 6.4
- ♦ Apple QuickTime 4.1 or later
- ♦ Netscape LiveAudio (for NN3 and NN4)

The main goal of the library is to act as an API (Application Programming Interface) between your scripts and the three plug-ins. Your scripts issue one command, and the library figures out which plug-in is installed and how that particular command must be communicated to the installed plug-in. Additional verification takes place in the initialization routine to verify that a valid plug-in is installed in the user's browser.

The HTML side

Depending on the browser and operating system that you're using, one of two tags can be used to put the plug-in's powers into the page. With the plug-in embedded within the page (even if you don't see it), the plug-in becomes part of the document's object model, which means that your scripts can address it.

Using EMBED

The preferred way to embed such content into a page for NN (all OSes) and IE/Mac is to use the `<EMBED>` tag. Even though the W3C HTML standard does not recognize the EMBED element, it has been a part of browser implementations since the first embeddable media. The element is also a bit of a chameleon, because beyond a common set of recognized attributes, such as the SRC attribute that points to the content file to be loaded into the plug-in, its attributes are extensible to include items that apply only to a given plug-in. Uncovering the precise lists of attributes and values for a plug-in is not always easy, and frequently requires digging deeply into the developer documentation of the plug-in's producer. It is not unusual for a page author to anticipate that multiple plug-ins could play a particular kind of data (as is the case in the audio examples later in this chapter). Therefore, a single EMBED element may include attributes that apply to more than one plug-in. You have to hope that the plug-ins' developers chose unique names for their attributes or that like-named attributes mean the same thing in multiple plug-ins. Any attributes that a plug-in doesn't recognize are ignored.

Typical behavior for a plug-in is to display some kind of controller or other panel in a rectangle associated with the media. You definitely need to specify the HEIGHT and WIDTH attribute values of such an EMBED element if it is to display visual media (some video plug-ins let you hide the controls, while still showing the viewing area). For audio, however, you can specify a one-pixel value for both dimensions, and leave the controls to your HTML content. Browsers that recognize style sheets can also set EMBED elements to be invisible.

As an example of what an EMBED element may look like, the following is adapted from Listing 44-9. The example includes attributes that apply to QuickTime and LiveAudio and is formatted here for ease of readability.

```
<EMBED NAME="jukebox"
  HEIGHT=1
  WIDTH=1
  SRC="Beethoven.aif"
  HIDDEN=TRUE
  AUTOSTART=FALSE
  AUTOPLAYT=FALSE
  ENABLEJAVASCRIPT=TRUE
  MASTERSOUND>
</EMBED>
```

After the page loads and encounters this tag, the browser reaches out to the server and loads the sound file into the plug-in, where it sits quietly until the plug-in is instructed to play it.

IE/Windows OBJECT

In the IE/Windows camp, the preferred way to get external media into the document is to load the plug-in (ActiveX control) as an object via the `<OBJECT>` tag. The OBJECT element is endorsed by the W3C HTML standard. In many ways the `<OBJECT>` tag works like the `<APPLET>` tag in that aside from specifying attributes that load the plug-in, additional nested PARAM elements let you make numerous settings to the plug-in while it loads, including the name of the file to pre-load. As with a plug-in's attributes, an object's parameters are unique to the object and are documented (somewhere) for every object intended to be put into an HTML page.

IE/Windows has a special (that is, far from intuitive) way it refers to the plug-in program: through its class ID (also known as a GUID). You must know this long string of numbers and letters in order to embed the object into your page. If you are having difficulty getting this information from a vendor, see Chapter 32 for tips on how to hunt for the information yourself. There, you also discover how to find out what parameters apply to an object.

The following example is an OBJECT element that loads the Windows Media Player 6.x plug-in (ActiveX control) into a page. The example is adapted from Listing 44-9.

```
<OBJECT ID="jukebox" WIDTH="1" HEIGHT="1"
CLASSID="CLSID:22d6f312-b0f6-11d0-94ab-0080c74c7e95"
CODEBASE="#Version=6,0,0,0">
<PARAM NAME="FileName" VALUE="Beethoven.aif">
<PARAM NAME="AutoStart" VALUE="false">
</OBJECT>
```

When you compare the EMBED and OBJECT approaches, you can see many similar properties and values, which are just expressed differently (for example, attributes versus PARAM elements).

Using EMBED and OBJECT together

Because a public Web page must usually appeal to a broad range of browsers, you should design such a page to work with as many browsers as possible. For the convenience of your scripting (and especially if you use the audio playback API described later in this chapter), referring to a plug-in object by the same identifier is helpful, whether it is loaded via an EMBED or OBJECT element.

To the rescue comes a handy behavior of the OBJECT element. It is designed in such a way that you can nest the associated EMBED element inside the OBJECT element's tag set. If the browser doesn't know about the OBJECT element, that element is ignored, but the EMBED element is picked up. Similarly, if the browser that knows about the OBJECT element fails to load the plug-in identified in its attributes, the nested EMBED elements also get picked up. Therefore, you can combine the OBJECT and EMBED elements as shown in the following example, which combines the two previous examples:

```
<OBJECT ID="jukebox" WIDTH="1" HEIGHT="1"
CLASSID="CLSID:22d6f312-b0f6-11d0-94ab-0080c74c7e95"
CODEBASE="#Version=6,0,0,0">
<PARAM NAME="FileName" VALUE="Beethoven.aif">
<PARAM NAME="AutoStart" VALUE="false">
  <EMBED NAME="jukebox"
    HEIGHT=1
    WIDTH=1
    SRC="Beethoven.aif"
    HIDDEN=TRUE
    AUTOSTART=FALSE
    AUTOPLAY=FALSE
    ENABLEJAVASCRIPT=TRUE
    MASTERSOUND>
  </EMBED>
</OBJECT>
```

Notice that the identifier assigned to the `ID` of the `OBJECT` element and to the `NAME` of the `EMBED` element are the same. Because only one of these two elements will be valid in the document, you have no conflict of like-named elements.

Validating the plug-in

As described at length in Chapter 32, you may need to validate the installation of a particular plug-in before the external media will play. This validation is even more vital if you want to control the plug-in from scripts, because you must have the right controlling vocabulary for each scriptable plug-in.

The coordination of plug-in and data type is not a big issue in IE/Windows, because your `OBJECT` element explicitly loads a known plug-in, even if the computer is equipped to play the same data type through a half-dozen different ActiveX controls. But in NN (and IE/Mac, although plug-ins are not scriptable there at least through Version 5), the association of a plug-in with a particular MIME type (data type of the incoming media) is perhaps a bit too automatic. It is not uncommon for plug-in installation programs to gobble up the associations of numerous MIME types. Knowledgeable users, who can fathom the nether worlds of browser preferences, can manually change these associations, but your scripts cannot direct a browser to use a specific plug-in to play your media unless the plug-in is already enabled for your media's MIME type. The more common and open your media's MIME type is (particularly audio and video), the more of a potential problem this presents to you. *Caveat scriptor.*

With these warnings in mind, review the approaches to checking the presence of a plug-in and its enabled status by way of the `mimeType`s and `plugIns` objects described in Chapter 32. You see some of the routines from that chapter put to use in a moment.

The API approach

In this section, you see one version of an API that can be used to accomplish simple audio playback activities in a page through three different plug-in technologies (Windows Media Player 6, Apple QuickTime, and Netscape LiveAudio). Your scripts issue one command (for example, `play(1)`), and the API sends the precise command to the plug-in being used in the user's browser. At the same time, the API has its own initialization routine, which it uses not only to validate the plug-in being used, but alerts users of ill-equipped browsers with a relevant message about why their browser can't get the most out of the page.

This API is far from the be-all, end-all library, although you will see that it does quite a bit as-is. The code is offered as a starting point for your further development. Such development may take the shape of adding more operations to the API or adding capabilities for additional scriptable plug-ins. For example, while the API as shown supports Windows Media Player 6, Microsoft continues to upgrade the Player to new versions (with new GUIDs for your `OBJECT` tags) that have new command vocabularies. There is no reason that the API cannot be extended for new generations of Windows Media Player, while maintaining backward compatibility for the Version 6 generation.

You can find the complete API code on the CD-ROM within the folder of example listings for this chapter. The API file is named `DGAudioAPI.js`. Check out the following high points of this library.

Loading the library

Adding the library to your page is no different from any external .js library file. Include the following tag in the HEAD of your page:

```
<SCRIPT LANGUAGE="JavaScript" SRC="DGAudioAPI.js"></SCRIPT>
```

Except for two global variable initializations, no immediate code runs from the library. All of its activity is invoked from event handlers or other script statements in the main page.

Initializing the library

The first job for the library is to validate that your sounds have one of the three known plug-in technologies available. Before the library can do this, all loading of the OBJECT or EMBED elements must be concluded so that the objects exist for the initialization routine to examine. Therefore, use the onLoad event handler in the BODY to invoke the `initAudioAPI()` function. Parameters to be passed to this function are vital pieces of information.

Parameter values consist of one or more two-element arrays. The first value is a string of the identifier, which is assigned to the OBJECT and EMBED elements (recall that they are the same identifiers); the second value is a string of the MIME type. Getting the desired value may take some trial and error if you aren't familiar with MIME type terminology. Use the Edit/Preferences/Applications dialog box window listings in NN as a guide in finding the name of a MIME type based on the file name extension of the media file.

The following is an excerpt from Listing 44-9, which shows how the `jukebox` player object is initialized for the `audio/x-aiff` MIME type (all sound files for examples in this chapter have the `.aif` file name extension):

```
onLoad="initAudioAPI(['jukebox', 'audio/x-aiff'])"
```

Notice how the square bracket literal array syntax is used both to create the array of two values while passing them as parameters to the function. NN uses the MIME type to make sure that the plug-in that fired up as a result of the EMBED element is enabled for the MIME type.

As you see in Listing 44-10 (much later in this chapter), the `initAudioAPI()` function lets you initialize multiple player objects, each one with its own MIME type, if necessary. Each object and MIME type pair are passed as their own array. For example, the following initializes the library for two different embedded plug-in objects, although both have the same MIME type:

```
onLoad="initAudioAPI(['cNatural', 'audio/x-aiff'], ['cSharp', 'audio/x-aiff'])"
```

When the function receives multiple arrays, it loops through them, performing the initializations in sequence. The `initAudioAPI()` function follows:

```
function initAudioAPI() {
    var args = initAudioAPI.arguments
    var id, mime
    for (var i = 0; i < args.length; i++) {
        // don't init any more if browser lacks scriptable sound
        if (OKToTest) {
            id = args[i][0]
            mime = args[i][1]
        }
    }
}
```

```

        players[id] = new API(id, mime)
        players[id].type = setType(id, mime)
    }
}

```

Notice that parameter variables are not explicitly declared for the function, but are, instead, retrieved via the `arguments` property of the function. The global `OKToTest` flag, initialized to `true` when the library loads, is set to `false` if the validation of a plug-in fails. The conditional construction here prevents multiple alerts from appearing when multiple plug-in and MIME type parameters are passed to the initialization function.

Sound player API objects

One of the jobs of the initialization routine is to create a player object for each plug-in identifier. The object's constructor is as follows:

```

// AudioAPI object constructor
function API(id, mime) {
    this.id = id
    this.type = "" // values can be "isLA","isMP","isQT"
    this.mimeType = mime
    this.play = API_play
    this.stop = API_stop
    this.pause = API_pause
    this.rewind = API_rewind
    this.load = API_load
    this.getVolume = API_getVolume
    this.setVolume = API_setVolume
}

```

The object becomes a convenient place to preserve properties for each sound controller, including which type of plug-in it uses (described in a moment). But the bulk of the object is reserved for assigning methods—the methods that your main page's scripts invoke to play and stop the player, adjust its volume, and so on. The method names to the left of the assignment statements in the object constructor are the names your scripts use; the functions in the library (for example, `API_play()`) are the ones that send the right command to the right plug-in.

Each of these objects (even if there is only one for the page) is maintained in a hash table-like array (named `players[]`) in the library. The plug-in object's identifier is the string index for the array entry. This provides the gateway to your page's scripts. For example, if you initialize the library with a single identifier, `jukebox`, you access the methods of the library's `jukebox`-related player object through the array and the identifier:

```
players["jukebox"].rewind()
```

Plug-in checking

One more part of the initialization routine inside the library is a call to the `setType()` function, which ultimately assigns a value to the `players[]` object type property. For a valid plug-in, the value of the type property can be `isLA` (LiveAudio), `isMP` (Windows Media Player), `isQT` (QuickTime), or an empty string. Listing 44-8 shows code for the `setType()` function and some supporting functions.

Listing 44-8: setType() and Supporting Functions from DGAudioAPI.js

```

function setType(id, mime) {
    var type = ""
    var errMsg = "This browser is not equipped for scripted sound.\n\n"
    var OS = getOS()
    var brand = getBrand()
    var ver = getVersion(brand)
    if (brand == "IE") {
        if (ver > 4) {
            if (document.all(id) && document.all(id).HasError) {
                errMsg = document.all(id).ErrorDescription
            } else {
                if (OS == "Win") {
                    if (document.all(id) && document.all(id).CreationDate != "") {
                        return "isMP"
                    } else {
                        errMsg += "Expecting Windows Media Player Version 6.4."
                    }
                } else {
                    errMsg += "Only Internet Explorer for Windows is supported."
                }
            }
        } else {
            errMsg += "Only Internet Explorer 4 or later for Windows is
supported."
        }
    } else if (brand == "NN") {
        if ((ver >= 3 && ver < 4.6) || (ver >= 4.7 && ver < 6)) {
            if (mimeAndPluginReady(mime, "LiveAudio")) {
                return "isLA"
            }
            if (mimeAndPluginReady(mime, "QuickTime")) {
                qtVer = parseFloat(document.embeds[id].GetPluginVersion(), 10)
                if (qtVer >= 4.1) {
                    return "isQT"
                } else {
                    errMsg += "QuickTime Plugin 4.1 or later is required."
                }
            } else {
                errMsg += "Sound control requires QuickTime Plugin 4.1 "
                errMsg += "(or later) or LiveAudio "
                errMsg += "enabled for MIME type: \'' + mime + '\'."
            }
        } else {
            errMsg += "Requires Navigator 3.x, 4.0-4.5, or 4.7-4.9."
        }
    } else {
        errMsg += "This page is certified only for versions of Internet Explorer"
    }
}

```

Listing 44-8 (continued)

```
        errMsg == "and Netscape Navigator."
    }
    alert(errMsg)
    OKToTest = false
    return type
}

function getOS() {
    var ua = navigator.userAgent
    if (ua.indexOf("Win") != -1) {
        return "Win"
    }
    if (ua.indexOf("Mac") != -1) {
        return "Mac"
    }
    return "Other"
}

function getBrand() {
    var name = navigator.appName
    if (name == "Netscape") {
        return "NN"
    }
    if (name.indexOf("Internet Explorer") != -1) {
        return "IE"
    }
    return "Other"
}

function getVersion(brand) {
    var ver = navigator.appVersion
    var ua = navigator.userAgent
    if (brand == "NN") {
        if (parseInt(ver, 10) < 5) {
            return parseFloat(ver, 10)
        } else {
            // get full version for NN6+
            return parseFloat(ua.substring(ua.lastIndexOf("/") + 1))
        }
    }
    if (brand == "IE") {
        var IEOffset = ua.indexOf("MSIE ")
        return parseFloat(ua.substring(IEOffset + 5, ua.indexOf(";", IEOffset)))
    }
    return 0
}
```

The `setType()` function is an extensive decision tree that uses clues from the `navigator.userAgent` and `navigator.appVersion` properties to determine what environment is currently running. For each environment, plug-in detection takes

place to verify that either the desired Windows ActiveX object is installed in IE or that one of the acceptable plug-ins is running in NN. All of the detection code is taken from Chapter 32. One of the advantages of such a detailed decision tree is that if a decision branch fails, it is for a reasonably specific reason—enough detail to advise the user intelligently about why the current browser can't do what the page author wants it to do.

Invoking methods

Establishing the `players[]` object type is a critical operation of this library, because all subsequent operation depends on the type being set. For example, to perform the action of rewinding the sound to the beginning, your script invokes the following statement:

```
players["jukebox"].rewind()
```

This, in turn invokes the library's `API_rewind()` function:

```
function API_rewind() {
    switch (this.type) {
        case "isLA" :
            document.embeds[this.id].stop()
            document.embeds[this.id].start_at_beginning()
            break
        case "isQT" :
            document.embeds[this.id].Stop()
            document.embeds[this.id].Rewind()
            break
        case "isMP" :
            if (document.embeds[this.id]) {
                document.embeds[this.id].Stop()
                document.embeds[this.id].CurrentPosition = 0
            } else {
                document.all(this.id).Stop()
                document.all(this.id).CurrentPosition = 0
            }
            break
        default:
    }
}
```

Each of the three plug-ins covered in this API has an entirely different way to perform (or simulate) a rewinding of the current sound to the beginning. The `type` property of the `players[]` object invoked by your script determines which branch of the `switch` statement to follow. For each plug-in type, the appropriate document object model reference and the plug-in-specific property or method is accessed. The identifier passed as a parameter to the initialization routine continues to play a role, providing the identifier to the actual DOM object that is the plug-in controller (for example, an index to the `document.embeds[]` array).

The library contains a function just as the one you just saw for each of the seven methods assigned to `players[]` objects. They remain invisible to the user and to you as well, because you work only with the simpler `players[]` object method calls, regardless of plug-in.

**Note**

If the Windows Media Player detects a problem with the audio hardware, it doesn't always reflect the error in the object until after all `onLoad` event handler functions finish executing. This weirdness prevents the error checking from being performed where it should be, in the `setType()` function. Therefore, error checking for this possibility is performed in the API branch that commands the Media Player to play the currently loaded sound.

Extending the library

Adding more plug-in types to the library requires modification in two areas. The first is to the `setType()` function's decision tree. You have to determine where in the tree the plug-in is best detected. For another Windows Media Player, for instance, it would be along the same branch that looks for the Version 6 player.

You then need to locate the properties and methods of the new plug-in for basic operations covered in the library (play, stop, and so on). For each of the action functions, you add another case for your newly defined type. Your main Web page scripts should not require any modification (although your OBJECT and/or EMBED tag attributes may change to accommodate the new plug-in).

Building a jukebox

The first example that utilizes the `DGAudioAPI.js` library is a jukebox that provides an interface (admittedly not pretty—that's for you to whip up) for selecting and controlling multiple sound files with a single plug-in tag set. The assumption for this application is that only one sound at a time need be handy for immediate playing.

Listing 44-9 shows the code for the jukebox. All sound files specified in the example are in the same folder as the listing on the companion CD-ROM (the AIFF-format files sound better in some plug-ins than others, so don't worry about the audio quality of these demo sounds).

Listing 44-9: A Scripted Jukebox

```

<SCRIPT LANGUAGE="JavaScript" SRC="DGAudioAPI.js"></SCRIPT>
<SCRIPT>
// make sure currently selected tune is preloaded
function loadFirst(id) {
    var choice = document.forms[0].musicChoice
    var sndFile = choice.options[choice.selectedIndex].value
    players[id].load(sndFile)
}
// swap tunes
function changeTune(id, choice) {
    players[id].load(choice.options[choice.selectedIndex].value)
}
// control and display volume setting
function raiseVol(id) {
    var currLevel = players[id].getVolume()
    currLevel += Math.ceil(Math.abs(currLevel)/10)
    players[id].setVolume(currLevel)
}
```

```

        displayVol(id)
    }
    function lowerVol(id) {
        var currLevel = players[id].getVolume()
        currLevel -= Math.floor(Math.abs(currLevel)/10)
        players[id].setVolume(currLevel)
        displayVol(id)
    }
    function displayVol(id) {
        document.forms[0].volume.value = players[id].getVolume()
    }
</SCRIPT>

```

You can see the user interface in Figure 44-5. One SELECT element contains a list of three possible choices. Most of the interface, however, consists of buttons that ultimately invoke methods of the current plug-in.

Figure 44-5: The jukebox page

Two functions are invoked by the `onLoad` event handler besides the initialization routine of the library. The `loadFirst()` function finds out which of the items in the `SELECT` element is chosen when the page loads, and it makes sure that the file is pre-loaded into the plug-in. This functionality is provided in case the user makes a choice and should use the Back button or history to return to the page. In some browsers, the `SELECT` element will be set to its most recent setting, so the `loadFirst()` function simply gets everything ready.

The second `onLoad` function call is to `displayVol()`. This function works its way through the library to read the volume setting of the plug-in and displays the resulting value in a text box in the form. Not all plug-ins use the same scale or numbering system for their volume controls. Windows Media Player 6, for instance, uses very large negative numbers, while QuickTime and LiveAudio are on different, positive scales. The other volume-related functions simply increase or decrease the current setting by 10 percent in response to clicking the associated buttons in the interface.

All functions defined for this page are designed to be as generalizable as possible. Thus, the identifier of the plug-in is passed as a parameter to each. If another plug-in were added to this page, the same functions could be used without modification, provided calls to the functions passed the identifier of the other plug-in.

All of the button controls are pretty straightforward except the Play button's `onClick` event handler. It invokes the `players[id].play()` method, but that method requires a parameter of how many times the sound should be played. In this user interface, a `SELECT` element controls that information. Getting the value of the selected item creates a lengthy reference, but that's what is taking up so much space in the parameter slot of the `play()` method call.

Embedding multiple sounds

The final example of embedded media serves as a base on which you can build a page that needs to play multiple sounds without the user explicitly loading them. For example, you may have buttons generate different sounds after users click them (I'm not recommending this interface, but that won't necessarily stop you). Figure 44-6 shows you the simple five-key piano keyboard. The page loads five different sounds into the page, one for each note (actual piano sounds in this case). Each sound was recorded for about four seconds, so that you can get the action of attack and delay, just like a real piano. If you mouse down on a key, the sound plays for up to four seconds (getting softer all the time) or until you mouse up on the key (the attack time on the sample sounds on the CD-ROM is not instantaneous, so you may have to hold a key down for a fraction of a second to start the sound). The colors of the keys also change slightly to provide further user feedback to the action.

Figure 44-6: Controller for five sounds

Thanks to the `DGAudioAPI.js` library, very little code in this page is associated with the sounds. Far more is involved with the image swaps and the loading of the five plug-ins. Listing 44-10 shows the code for the page.

```

Perhaps the trickiest part of this entire demonstration lies in the way the keyboard art and user interface are created. Because the white keys are not

rectangular, the black key art is dropped atop the white keys by way of positioned elements (which become layer objects in NN4). The visual reward is worth the extra pain of managing references to the images within NN4 layers.

When you use the page, you may notice a slight delay in getting the sound to be heard after pressing down on a key. On older, slower machines, this delay is even more noticeable. Take this behavior into account when designing interactive sound.

Scripting Java Classes Directly

LiveConnect, as implemented in NN3 and NN4, allows scripts to access Java classes as if they were part of the JavaScript environment. Because you need to know your way around Java before programming Java classes directly from JavaScript, I won't get into too much detail in this book. Fortunately, the designers of JavaScript have done a good job of creating JavaScript equivalents for the most common Java language functionality, so there is not a strong need to access Java classes on a daily basis.

To script Java classes, it helps to have a good reference guide to the classes built into Java. Though intended for experienced Java programmers, *Java in a Nutshell* (O'Reilly & Associates, Inc.) offers a condensed view of the classes, their constructors, and their methods.

Java's built-in classes are divided into major groups (called *packages*) to help programmers find the right class and method for any need. Each package focuses on one particular aspect of programming, such as classes for user interface design in application and applet windows, network access, and basic language constructs, such as strings, arrays, and numbers. References to each class (object) defined in Java are "dot" references, just as in JavaScript. Each item following a dot helps zero-in on the desired item. As an example, consider one class that is part of the base language class. The base language class is referred to as

```
java.lang
```

One of the objects defined in `java.lang` is the `String` object, whose full reference is

```
java.lang.String
```

To access one of its methods, you use an invocation syntax with which you are already familiar:

```
java.lang.String.methodName([parameters])
```

To demonstrate accessing Java from JavaScript, I call upon one of Java's `String` object methods, `java.lang.String.equalsIgnoreCase()`, to compare two strings. Equivalent ways are available for accomplishing the same task in JavaScript (for example, comparing both strings in their `toUpperCase()` or `toLowerCase()` versions), so don't look to this Java demonstration for some great new powers along these lines.

Before you can work with data in Java, you have to construct a new object. Of the many ways to construct a new `String` object in Java, you use the one that accepts the actual string as the parameter to the constructor:

```
var mainString = new java.lang.String("TV Guide")
```

At this point, your JavaScript variable, `mainString`, contains a reference to the Java object. From here, you can call this object's Java methods directly:

```
var result = mainString.equalsIgnoreCase("tv Guide")
```

Even from JavaScript, you can use Java classes to create objects that are Java arrays and access them via the same kind of array references (with square brackets) as JavaScript arrays. In a few cases, you can use Java classes to obtain additional information about the user environment, such as the user's IP address (but not e-mail address). The process involves a couple of Java class calls, as follows:

```
var localhost = java.net.InetAddress.getLocalHost()  
var IP = localhost.getHostAddress()
```

The more you work with these two languages, the more you see how much Java and JavaScript have in common.

Debugging Scripts

One of the first questions that an experienced programmer asks about a programming environment is what support is there for debugging code. Even the best coders in the world make mistakes when they draft programs. Sometimes, the mistakes are a mere slip of a finger on the keyboard; other times, they result from not being careful with expression evaluation or object references. The cause of the mistake is not the issue: finding the mistake and getting help to fix it is.

Some debugging tools are available for the latest browsers. For the most part, they have come from the browser makers themselves, or they are tied very closely to a particular authoring environment. Some of these tools are very quirky; others require significant investments in authoring environments. Discussion about debugging tools in this chapter, however, focuses on simple tools provided on the companion CD-ROM. By understanding the true meaning of error messages and working out the problem with the tools provided here, you should be able to overcome your bugs.

Syntax versus Runtime Errors

As a page loads into a JavaScript-enabled browser, the browser attempts to create an object model out of the HTML and JavaScript code in the document. Some types of errors crop up at this point. These are mostly syntax errors, such as failing to include a closing brace after a function's statements. Such errors are structural in nature, rather than about values or object references.

Runtime errors involve failed connections between function calls and their functions, mismatched data types, and undeclared variables located on the wrong side of assignment operators. Such runtime errors can occur as the page loads if the script lines run immediately as the page loads. Runtime errors located in functions won't crop up until the functions are called — either as the page loads or in response to user action.

45

CHAPTER

In This Chapter

Identifying the type of error plaguing a script

Interpreting error messages

Preventing problems before they occur

Because of the interpreted nature of JavaScript, the distinction between syntax and runtime errors blurs. But as you work through whatever problem halts a page from loading or a script from running, you have to be aware of differences between true errors in language and your errors in logic or evaluation.

Error Message Notification

As the browsers have evolved through several generations, the ways in which script errors are reported to the user (and to you as the author) have also changed. The biggest changes came in IE4/Windows and NN4.5. Prior to those versions, script errors always displayed some kind of alert dialog box with information about the error. Because these alerts could confuse non-technical users, the newer browsers (except for IE/Mac) are much more subtle about the presence of errors. In fact the notification mechanism is so subtle, that it is easy to miss the fact that a script error has occurred. Even if you do notice, you must then exercise your mouse a bit more to view the details.

When a script error occurs in IE4+/Windows, the statusbar displays a yellow alert icon plus a brief text message indicating that an error has occurred. A syntax error that occurs while the page loads usually signifies that the page has loaded, but with errors. A runtime error's message simply indicates that an error occurred. To view details about the error, you must double-click the yellow icon in the statusbar. The default appearance of the error message alert dialog box window includes a button named Show Details. Clicking this button expands the window to reveal whatever details the browser is reporting about the error. If you leave the window expanded, the next time it opens, it will also be expanded. It is a good idea for scripters to also check the box that forces the browser to show the error dialog box whenever an error occurs. This is simply a shortcut to manually double-clicking the statusbar error icon.

Netscape console windows

For NN4 browsers starting with NN4.5, a user receives error notification through a message in the statusbar. The instructions there indicate how to view the error details: If you type

```
javascript:
```

into the toolbar's Location box or into the dialog box that lets you open a new page, an entirely new, non-modal window appears. This window is called the Communicator Console. In contrast to the one message per window approach of IE, the Communicator Console window continues to record all script errors in sequence (in a scrolling frame), even when the Console window is closed. You can keep this window open all the time, and simply bring it to the front whenever you need to view errors. If you are developing on a large video monitor, you can let the Console window stick out to the right of the browser window. If an error occurs, not only does the message appear in the browser statusbar, but you'll also see the scrollbar of the Console window's top frame appear — an even more explicit indication that an error occurred (assuming you click the Clear Console button every time you are ready to try another test run).

Netscape changed the name of the window for NN6, now calling it the JavaScript Console. Opening this window is less cryptic than before: Choose Tasks/Tools/JavaScript Console from the menu bar. NN6 does not provide notification of errors in the statusbar, so it is up to you to be vigilant for something running amok. This is all the more reason to keep the JavaScript Console window open while you are writing and debugging your scripts. Even if things appear to be OK, periodically check the Console window to be sure.

Multiple error messages

The modality of IE error message alert dialog boxes tends to force just one message to appear. In other words, when the first error occurs, the browser stops recording further errors. In NN, however, it is not uncommon for multiple errors to be listed (or, in older versions, multiple error windows to show up). But you need to understand how to treat these multiple errors to get to the root of the problem.

The usual reaction is to look at the last message to appear in the sequence. That, however, is usually the error message least likely to lead you to the true problem. Error messages are dumped to the NN Console window in the order in which they occur. This means that the first error in the list is the most important error message of them all. More than likely, the first error points to a problem that throws off the rest of the script, thus triggering all of the other error messages. For example, if a statement that initializes a variable has a syntax error in it, all other statements that rely on that variable will fail, because the variable appears to be undefined.

When you encounter multiple errors, don't start any serious debugging until you locate the first error message. You must tackle this one before any others. The solution to the first one may cause the other errors to go away. This is all the more reason, when authoring in NN4.5+, to keep the Console window open, and clear it before loading any page or executing any scripts.

Error Message Details

Error reporting comes in three flavors depending on the browser: NN, IE/Windows, IE/Mac. One of these groups may be better (that is, more accurate and explicit) at reporting some kinds of errors than the other groups. By and large, however, you can count on error details to include three basic clues to help you track down the error: the file in which the error occurred, the location of the error within the source code, and a textual description of the error.

Error file name

Although IE/Mac error messages do not explicitly reveal the name of the file whose source code contains the error, in practice, only the NN browsers do the best job of telling the truth. Of course, when the script and HTML are all on one page, it doesn't require a brain surgeon to know that the error occurs from that page's source code. But if you link in external `.js` libraries, the NN browsers provide the URL to the `.js` file. IE/Windows, on the other hand, indicates the HTML page that loads the external library, making it difficult to know precisely where the error is.

Error location

All browsers provide a source code line number and character position where the error supposedly occurs. For self-contained pages with no dynamically created content, the reporting tends to be accurate (also see the IE “Object expected” error message details described later in this chapter), but the accuracy is much closer in NN browsers than IE. And if your page links in an external library, the line number provided by IE/Windows and IE/Mac is practically useless. The sense you get is that the lines of the `.js` file become embedded within the main page’s script, but how that is supposed to help an author find the precise problem line is a mystery — even the most feature-laden text editor knows only how to display line numbers for a single document.

NN browsers, however, not only point to the correct `.js` file, but to the line number within that file. You are much more likely to get to the root of a problem, especially in an external `.js` file, through NN error messages.

Line number reporting has improved with each browser generation, but anomalies still exist. Perhaps the most egregious is the tendency for IE to report a problem at a line number whose source code is HTML with an event handler. The problem, it turns out, will be somewhere in the function being invoked by the event handler. Another possibility in all browsers is that the line number being reported is below the line that contains the problem. Consider the following simple source code listing (with line numbers from the source code editor) that intentionally contains a syntax error:

```
1:  <HTML>
2:  <HEAD>
3:  <SCRIPT LANGUAGE="JavaScript">
4:  function tarzan() {
5:      var x = 1
6:
7:  function jane() {
8:      var y = 3
9:  }
10: </SCRIPT>
11: </HEAD>
12: <BODY>
13: Hello.
14: </BODY>
15: </HTML>
```

When you load this page into browsers, all of them report a problem with a missing right brace (NN is a bit more explicit with its message, indicating that a right brace is missing after a function body). But where do the browsers point to the error? By looking at the code as a human, you can see that the missing brace belongs in Line 6. But now examine the code from the point of view of a script interpreter engine: It sees the opening brace on Line 4, and then a new function declaration starting on Line 7. To the interpreter, this means that the `jane()` function is probably nested inside the `tarzan()` function, and it is the `tarzan()` function that is lacking the right brace following the `jane()` function. Therefore, the error line number comes in at Line 10 (although IE5/Mac reports Line 9). Your scripts won’t likely be this simple, so the distance between the reported error line number and the location of the actual problem can be substantial and difficult to spot without using some of the tips and tools described later in this chapter.

IE sometimes has a nasty habit of identifying the location of the problem at Line 1, Character 1. All this means is that you need to put your detective skills to work that much harder. Common causes for this behavior are references to HTML objects that don't exist (or there is a mismatch between the identifier of the element and your script reference to it) and errors that affect global functions or window methods. To find the genuine problem line, you can use tracing techniques described later in this chapter.

Error message text

Because so many permutations exist of the potential errors you can make in scripts and the ways the JavaScript interpreters in different browsers regard these errors, presenting hard-and-fast solutions to every JavaScript error message is impossible. What I can do, however, is list the most common and head-scratch-inducing error messages and relate the kinds of non-obvious problems that can trigger such messages.

“Object expected”

This error message is often one of the least helpful that you see in IE. The line number associated with the message typically points to a line in the source code that invokes a function. If you define event handlers as attributes of element tags, the line number being reported may correspond to the line containing that HTML tag.

The most obvious problem is that the function being invoked is not regarded as a valid function in the page (the “object” referred to here is the function object). This problem can be the result of an HTML or script error earlier in the document. The problem can also be the result of some error in the function itself that failed to let the interpreter treat the function as a genuine function object. Most typically, these kinds of problems are detected as syntax errors while the page loads (for example, an imbalanced set of parentheses or braces), but not always.

As a first-strike tactic, you need to determine if the function is being invoked at all. By placing an alert in the first line of the function and triggering the function, you can see if script execution is reaching that point. If that works okay, then move the alert downward through the function to find out where the error is actually being triggered. The line before the alert that fails is the likely culprit.

“Expected <something>”

This message usually points straight at the problem line. Most of the “things” that the statement expects are self-explanatory. If a right parenthesis is missing from a pair, that is the “thing” shown to be expected. Detecting in the message the difference between a brace and parenthesis isn't always easy, so look at the message carefully. Not quite as intuitive is when the message says “Expected identifier”. This error refers to an expression that typically is trying to use a reserved word as a variable name. Look into Appendix B for a list of reserved words, none of which you may use as names of things or variables.

“<Something> is undefined”

This message is fairly easy to understand, yet at times difficult to diagnose. For variable names, the message usually means that you have an uninitialized variable name sitting in the position of a right-hand operand or a unary operand. This variable name has not been declared or assigned with any value prior to this erroneous statement. Perhaps you're attempting to use a variable name that has been initialized only as a local variable in another function. You may also have intended the

right-hand value to be a string, but you forgot to enclose it in quotes, forcing JavaScript to look upon it as a reference to something. Another possibility is that you misspelled the name of a previously declared variable. JavaScript rightly regards this item as a new, undeclared variable. Misspellings, you will recall, include errors in upper- and lowercase in the very case-sensitive JavaScript world.

If the item is a function name, you may have to perform a bit of detective work. Though the function may be defined properly, a problem in the script above the function (for example, imbalanced braces) makes JavaScript fail to see the function. In other cases, you may be trying to invoke a function in another window or frame but forgot to include the reference to that distant spot in the call to the function.

A less likely case, but a confusing one to diagnose, is when you are assembling string versions of function calls or array references out of literal strings and variable values. The following simplified example is assembling a string that is a function call to be triggered by `setTimeout()`:

```
function doA() {
    var x = "joe"
    setTimeout("doB(" + x + ")", 5000)
}
```

Even though the value of `x` is a string when it is concatenated to the call to the `doB()` function, the value gets evaluated as if it were a variable name. An error crops up saying that “joe is undefined”. Because you want to pass the value of `x` as a parameter, you must nest its value inside a pair of quotes, as follows:

```
function doA() {
    var x = "joe"
    setTimeout("doB('" + x + "')", 5000)
}
```

The difference in the code is extremely subtle, but absolutely necessary.

“<Something> is not a function”

As with the preceding one, this error message can be one of the most frustrating, because when you look at the script, it appears as though you have clearly defined a function by that name, and you’re simply having an event handler or other running statement call that function. The first problems to look for are mismatched case of letters in the calling statement and function and the reuse of a variable or HTML object name by the function name.

This latter item is a no-no — it confuses JavaScript into thinking that the function doesn’t exist, even though the object name doesn’t have parentheses appended to it and the function does. I’ve also seen this error appear when other problems existed in the script above the function named in the error message, and the named function was the last one in a script.

In NN, this message appears when you attempt to invoke a function that is not implemented for a particular object. For example, if you attempt to use a W3C DOM method in NN4, the error reports that the method you tried to invoke “is not a function.”

“Object doesn’t support this property or method”

This IE message reports that a valid object does not provide support for a method you just attempted to invoke. In practice, this message rarely appears as the result of referencing an object’s nonexistent property, because the language

allows for extending an object's list of properties by assignment. If you do a lot of development in IE5+ for Windows, you may see a lot of this message when testing the page in IE5 for the Macintosh, whose complement of implemented object methods is somewhat smaller.

"Unterminated string literal"

"Unterminated string constant"

NN is far more helpful with this type of message, because along with the error message, it displays the code fragment that tripped the error. You will see the beginning (or all) of the string that is the culprit. If you simply forgot to close a string quote pair, the error most frequently appears when you try to concatenate strings or nest quoted strings. Despite the claim that you can nest alternating double and single quotes, I often have difficulties using this nesting method beyond the second nested level (single quotes inside a double-quoted string). At different times, I've gotten away with using a pair of `\` inline quote symbols for a third layer. If that syntax fails, I break up the string so that nesting goes no deeper than two layers. If necessary, I even back out the most nested string and assign it to a variable in the preceding line—concatenating it into the more complex string in the next line.

In the Windows 3.1 versions of Navigator, you may also see this error if a string value is longer than about 250 characters. But you can divide such a string into smaller segments and concatenate these strings later in the script with the add-by-value (`+=`) operator.

And in all versions of Navigator through NN4, avoid statements in scripts that extend for more than 255 characters. If you use a text editor that counts the column number as you type, use this measure as a guide for long statements. Break up long statements into shorter lines.

"Missing } after function body"

"Expected }"

This error usually is easy to recognize in a simple function definition because the closing brace is missing at the end of the function. But when the function includes additional nested items, such as `if...else` or `for` loop constructions, you begin dealing with multiple pairs of braces within the function. The JavaScript interpreter doesn't always determine exactly where the missing brace belongs, and thus it simply defaults to the end of the function. This location is a natural choice, I guess, because from a global perspective of the function, one or more of the right braces that ripple down to the end of the function usually are missing.

In any case, this error message means that a brace is missing somewhere in a function above the referenced line number. Do an inventory count for left and right braces and see whether a discrepancy occurs in the counts. One of those nested constructions is probably missing a closing brace. Some programmer-oriented text editors also include tools for finding balanced pairs of braces and parentheses.

"<Something> is not a number"

The variable name singled out in this error message is most likely a string or null value. The line of JavaScript that trips it up has an operator that demands a number. When in doubt about the data type of a variable destined for a math operation, use the `parseInt()` or `parseFloat()` functions to convert strings to numbers.

I have also encountered this error when it provides no clue about what isn't a number — the error message simply says, “is not a number.” The root of the problem ended up having nothing to do with numbers. A structural imbalance in the script triggered this bogus error message.

“<Something> has no property named . . .”

“<Something> has no properties”

When a statement trips this error message, an object reference has usually gone awry in an assignment or comparison expression. You probably attempted to reference a property of an object, but something is wrong with the object reference, or you're trying to retrieve a property that doesn't exist for that object. If the reference is an extended one, you may have to dig to find the precise problem with the reference. Consider the following two statements that attempt to access the `value` property of a button named `calcMe`:

```
document.forms.calcme.value
document.forms[0].calcme.value
```

The NN errors for these two statements would read “`document.forms.calcme` has no properties” and “`document.forms[0].calcme` has no properties”. Causes for the two errors are quite different. The obvious problem with them both may seem to be that the button's name is incorrectly referenced as `calcme` instead of `calcMe`. That, indeed, is the error for the second statement. But a more fundamental problem also plagues the first statement: the `document.forms` reference (a valid object, returning an array of forms) needs an array index in this instance, because it needs to look into a particular form for one of its objects. Unfortunately, both error messages look alike at first glance, and you cannot tell from them which statement has two errors and which has one.

But what you can do when this kind of error appears is use the reference that is returned with the error message to check your work. Start verifying the accuracy of your references from left to right. Later in this chapter, you see how to use the embeddable Evaluator tool to verify the existence of object references.

“<Something> is null or not an object”

This message is the IE version of the previous NN error message. A big difference is that the reference returned as part of the error message includes the complete reference. Therefore, a reference to a nonexistent `calcme` button in a form yields the error message “‘`document.forms[0].calcme.value`’ is null or not an object”. Your first instinct is to be suspicious of the `value` property part of the reference. The detective work to find the problem is the same as in the NN version: verify the reference piece by piece, working from left to right. Again, the embeddable Evaluator can assist in this task.

“<Something> has no property indexed by [i]”

Look carefully at the object reference in this error message. The last item has an array index in the script, but the item is not an array value type. Users commonly make this mistake within the complex references necessary for radio buttons and SELECT options. Make sure that you know which items in those lengthy references are arrays and which are simply object names that don't require array values.

“<Something> can't be set by assignment”

This error message tells you either that the property shown is read-only or that the reference points to an object, which must be created via a constructor function rather than by simple assignment.

“Test for equality (==) mistyped as assignment (=)? Assuming equality test.”

The first time I received this error, I was amazed by JavaScript's intelligence. I had, indeed, meant to use the equality comparison function (==) but had entered only a single equal sign. JavaScript is good at picking out these situations where Boolean values are required. In NN6, this message has been demoted to just a warning rather than an error.

“Function does not always return a value”

Often while designing deeply nested `if...else` constructions, your mind follows a single logic path to make sure that a particular series of conditions is met, and that the function returns the desired values under those conditions. What is easy to overlook is that there may be cases in which the decision process may “fall through” all the way to the bottom without returning any value, at which point the function must indicate a value that it returns, even if it is a 0 or empty (but most likely a Boolean value). JavaScript checks the organization of functions to make sure that each condition has a value returned to the calling statement. The error message doesn't tell you where you're missing the return statement, so you have to do a bit of logic digging yourself.

“Access disallowed from scripts at <URL> to documents at <URL>” **“Access is denied”**

These messages (NN and IE versions, respectively) indicate that a script in one frame or window is trying to access information in another frame or window that has been deemed a potential security threat. Such threats include any location object property or other information about the content of the other frame when the other frame's document comes from a protocol, server, or host that is different from the one serving up the document doing the fetching.

Even the best of intentions can be thwarted by these security restrictions. For example, you may be developing an application that blends data in cooperation with another site. Security restrictions, of course, don't know that you have a cooperative agreement with the other Web site, and you have no workaround for accessing a completely different domain unless you use signed scripts for NN (see Chapter 46) or an IE user has browser security levels set dangerously loose.

Another possible trigger for these errors is that you are using two different servers in the same domain or different protocols (for example, using `https:` for the secure part of your commerce site, while all catalog info uses the `http:` protocol). If the two sites have the same domain (for example, `giantco.com`) but different server names or protocols, you can set the `document.domain` properties of documents so that they recognize each other as equals. See Chapter 46 for details on these issues and the restrictions placed on scripts that mean well, but that can be used for evil purposes.

IE, especially Windows versions, frequently clamps down too severely on inter-window and inter-frame communication. Don't be surprised to encounter security problems trying to communicate between a main window and another window whose content is dynamically generated by scripts in the main window. This error can be incredibly frustrating. Sometimes, serving the main page from a server (instead of reading it from a local hard disk) can solve the problem, but not always. You are safest if the content of both windows or frames are HTML documents served from the same server and domain.

“Lengthy JavaScript still running. Continue?”

Although not a genuine error message, this NN3 alert dialog box provides a safeguard against inadvertent infinite loops and intentional ones triggered by JavaScript tricksters. Instead of permanently locking up the browser, NN3 — after processing a large number of rapidly executing script cycles — asks the user whether the scripts should continue. This error was not adopted in later versions of NN or ever implemented in IE.

“Unspecified error”

This completely unhelpful IE error message is not a good sign because it means that whatever error is occurring is not part of the well-traveled decision tree that the browser uses to report errors. All is not lost, however. That the browser has not crashed means that you can still attempt to get at the root of the problem through various tracing tactics described later in this chapter.

“Uncaught exception”

You may encounter these messages in NN6, although usually not as a result of your scripts unless you are using some of the browser's facilities to dive into inner workings of the browser. These messages are triggered by the browser's own programming code, and indicate a processing error that was not properly wrapped inside error trapping mechanisms. The details associated with such an error point to NN6's own source code modules and internal routines. If you can repeat the error and can do so in a small test case page, you are encouraged to submit a report to <http://bugzilla.mozilla.org>, the bug tracking site for the engine inside NN6.

“Too many JavaScript errors”

You may see this message in NN if it detects a runaway train generating errors uncontrollably. This message was far more important in the days of separate error windows, because a buggy repeat loop could cause NN to generate more error windows than it could do safely.

Sniffing Out Problems

It doesn't take many error-tracking sessions to get you in the save-switch-reload mode quickly. Assuming that you know this routine (described in Chapter 3), the following are some techniques I use to find errors in my scripts when the error messages aren't being helpful in directing me right to the problem.

Check the HTML tags

Before I look into the JavaScript code, I review the document carefully to make sure that I've written all my HTML tags properly. That includes making sure that all tags have closing angle brackets and that all tag pairs have balanced opening and

closing tags. Digging deeper, especially in tags near the beginning of scripts, I make sure that all tag attributes that must be enclosed in quotes have the quote pairs in place. A browser may be forgiving about sloppy HTML as far as layout goes, but the JavaScript interpreter isn't as accommodating. Finally, I ensure that the `<SCRIPT>` tag pairs are in place (they may be in multiple locations throughout my document) and that the `LANGUAGE="JavaScript"` attribute value has both of its quotes.

View the source

Your success in locating bugs by viewing the source in the browser varies widely with the kind of content on the page and the browser you use. Very frequently, authors place perhaps too much importance to what they see in the source window.

For a straight, no-frame HTML page, viewing the source provides a modicum of comfort by letting you know that the entire page has arrived from the server. Some versions of NN might flash a questionable HTML construction, but don't expect miracles.

Note: NN4 exhibits a notorious bug in the source view if your HTML tags include `STYLE` attributes for element-specific style sheets. You may "see double" in these lines, whereby the `STYLE` attribute appears to be repeated (although usually beginning with "TTYLE...") in what looks to be gibberish. This problem is a bug in the source viewer and does not accurately represent what the browser-rendering engine is using as source code.

Examining the source code for framesetting documents or individual frames, you must first give focus to the desired element. For an individual frame, click in the frame, and then right-click (or click and hold on the Mac) on the frame's background to get the contextual menu. One of the items should indicate a source view of the frame. To view the framesetter's source, press the Tab key until the Address/Location field of the browser is selected. Then choose to view the source from the Edit menu.

Where the source view would be most helpful, but often fails, is to display dynamically generated HTML. Your best chance will be for pages whose entire content is generated by script. This is about the only place you can appreciate the difference between `document.write()` and `document.writeln()`, because the latter puts carriage returns after the end of each string passed as a parameter to the method. The result is a more readable source view. Most recent browsers, with the exception of NN6, display the HTML as written by your script. NN4 does this in a window whose URL indicates the `wysiwyg:` protocol—an internal indication of dynamically generated content.

But when only part of the page is generated by script, few browsers combine the hard-wired and dynamic code in the source view. Instead, you see only the hard-wired HTML and scripts. To work around this for IE4+ and NN6, you can use the embeddable Evaluator and read the `innerHTML` property of any elements you want.

Intermittent scripts

Without question, the most common bug in Navigator 2.0x is the one that makes scripts behave intermittently. Buttons, for example, won't fire `onClick` event handlers unless the page is reloaded. Or, as a result of the same bug, sometimes a script runs and sometimes it doesn't. The problem here is that NN2 requires all `` tags to include `HEIGHT` and `WIDTH` attributes, even when the images are not scripted. Because doing so is good HTML practice anyway (it helps the browser's layout performance and is technically required according to the formal HTML specification), if

you include these attributes without fail throughout your HTML documents, you won't be plagued by intermittent behavior.

Scripts not working in tables

Tables have been a problem for scripts through NN3. The browser has difficulty when a `<SCRIPT>` tag is included inside a `<TD>` tag pair for a table cell. The workaround for this is to put the `<SCRIPT>` tag outside the table cell tag and use `document.write()` to generate the `<TD>` tag and its contents. I usually go one step further, and use `document.write()` to generate the entire table's HTML. This step is necessary only when executable statements are needed in cells (for example, to generate content for the cell). If a cell contains a form element whose event handler calls a function, you don't have to worry about this problem.

Timing problems

One problem category that is very difficult to diagnose is the so-called timing problem. There are no hard-and-fast rules that govern when you are going to experience such a problem. Very experienced scripters develop an instinct about when timing is causing a problem that has no other explanation.

A timing problem usually means that one or more script statements are executing before the complete action of an earlier statement has finished its task. JavaScript runs within a single thread inside the browser, meaning that only one statement can run at a time. But there are times when a statement invokes some browser service that operates in its own thread and therefore doesn't necessarily finish before the next JavaScript statement runs. If the next JavaScript statement relies on the previous statement's entire task having been completed, the script statement appears to fail, even though it actually runs as it should.

These problems crop up when scripts work with another browser window, and especially in IE for Windows (ironic in a way). In discussions in this book about form field validation, for example, I recommend that after an instructive alert dialog box notifies the user of the problem with the form, the affected text field should be given focus and its content selected. In IE/Windows, however, after the user closes the alert dialog box, the script statements that focus and select operate before the operating system has finished putting the alert away and refreshing the screen. The result is that the focused and selected text box loses its focus by the time the alert has finally disappeared.

The solution is to artificially slow down the statements that perform the focus and select operations. By placing these statements in a separate function, and invoking this function via the `window.setTimeout()` method, the browser catches its breath before executing the separate function — even when the delay parameter is set to zero. A similar delay is utilized when opening and writing to a new window, as shown in the example for `window.open()` in Chapter 16.

Reopen the file

If I make changes to the document that I truly believe should fix a problem, but the same problem persists after a reload, I reopen the file via the File menu. Sometimes, when you run an error-filled script more than once, the browser's internals get a bit confused. Reloading does not clear the bad stuff, although sometimes an unconditional reload (clicking Reload while holding Shift) does the job.

Reopening the file, however, clears the old file entirely from the browser's memory and loads the most recently fixed version of the source file. I find this situation to be especially true with documents involving multiple frames and tables and those that load external `.js` script library files. In severe cases, you may even have to restart the browser to clear its cobwebs, but this is less necessary in recent browsers. You should also consider turning off the cache in your development browser(s).

Find out what works

When an error message supplies little or no clue about the true location of a runtime problem, or when you're faced with crashes at an unknown point (even during document loading), you need to figure out which part of the script execution works properly.

If you have added a lot of scripting to the page without doing much testing, I suggest removing (or commenting out) all scripts except the one(s) that may get called by the document's `onLoad` event handler. This is primarily to make sure that the HTML is not way out of whack. Browsers tend to be quite lenient with bad HTML, so that this tactic won't necessarily tell the whole story. Next, add back the scripts in batches. Eventually, you want to find where the problem really is, regardless of the line number indicated by the error message alert.

To narrow down the problem spot, insert one or more alert dialog boxes into the script with a unique, brief message that you will recognize as reaching various stages (such as `alert("HERE-1")`). Start placing alert dialog boxes at the beginning of any groups of statements that execute and try the script again. Keep moving these dialog boxes deeper into the script (perhaps into other functions called by outer statements) until the error or crash occurs. You now know where to look for problems. See also an advanced tracing mechanism described later in this chapter.

Comment out statements

If the errors appear to be syntactical (as opposed to errors of evaluation), the error message may point to a code fragment several lines away from the problem. More often than not, the problem exists in a line somewhere above the one quoted in the error message. To find the offending line, begin commenting out lines one at a time (between reloading tests), starting with the line indicated in the error message. Keep doing this until the error message clears the area you're working on and points to some other problem below the original line (with the lines commented out, some value is likely to fail below). The most recent line you commented out is the one that has the beginning of your problem. Start looking there.

Check runtime expression evaluation

I've said many times throughout this book that one of the two most common problems scripters face is an expression that evaluates to something you don't expect (the other common problem is an incorrect object reference). In lieu of a debugger that would let you step through scripts one statement at a time while watching the values of variables and expressions, you have a few alternatives to displaying expression values while a script runs.

The simplest approaches to implement are an alert box and the statusbar. Both the alert dialog box and statusbar show you almost any kind of value, even if it is not a string or number. An alert dialog box can even display multiple-line values.

Because most expression evaluation problems come within function definitions, start such explorations from the top of the function. Every time you assign an object property to a variable or invoke a string, math, or date method, insert a line below that line with an `alert()` method or `window.status` assignment statement (`window.status = someValue`) that shows the contents of the new variable value. Do this one statement at a time, save, switch, and reload. Study the value that appears in the output device of choice to see if it's what you expect. If not, something is amiss in the previous line involving the expression(s) you used to achieve that value.

This process is excruciatingly tedious for debugging a long function, but it's absolutely essential for tracking down where a bum object reference or expression evaluation is tripping up your script. When a value comes back as being undefined or null, more than likely the problem is an object reference that is incomplete (for example, trying to access a frame without the `parent.frames[i]` reference), using the wrong name for an existing object (check case), or accessing a property or method that doesn't exist for that object.

When you need to check the value of an expression through a long sequence of script statements or over the lifetime of a repeat loop's execution, you are better off with a listing of values along the way. In the section "A Simple Trace Utility" later in this chapter, I show you how to capture trails of values through a script.

Using the embeddable Evaluator

As soon as a page loads or after some scripts run, the window contains objects whose properties very likely reveal a lot about the environment at rest (that is, not while scripts are running). Those values are normally disguised from you, and the only way to guarantee successful access to view those values is through scripting within the same window or frame. That's where the embeddable Evaluator comes in handy.

As you probably recall from Chapter 13 and the many example sections of Parts III and IV of this book, the code within the standalone Evaluator provides two text boxes for entry of expressions (in the top box) and object references (the bottom box). Results of expression evaluation and object property dumps are displayed in the Results textarea between the two input boxes. A compact version of The Evaluator is contained by a separate library version called `evaluator.js` (located in the Chapter 45 folder of listings on the companion CD-ROM). As you embark on any substantial page development project, you should link in the library with the following tag at the top of your HEAD section:

```
<SCRIPT LANGUAGE="JavaScript" SRC="evaluator.js"></SCRIPT>
```

Be sure to either have a copy of the `evaluator.js` file in the same directory as the document under construction or specify a complete file: URL to the library file on your hard drive for the SRC attribute.

Immediately above the closing BODY tag of your document, include the following:

```
<SCRIPT LANGUAGE="JavaScript">
printEvaluator()
</SCRIPT>
```

The `printEvaluator()` function draws a horizontal rule (HR) followed by the complete control panel of The Evaluator, including the codebase principle support for NN4+. From this control panel, you can reference any document object supported by the browser's object model or global variable. You can even invoke functions located in other scripts of the page by entering them into the top text box. Whatever references are available to other scripts on the page are also available to The Evaluator, including references to other frames of a frameset and even other windows (provided a reference to the newly opened window has been preserved as a global variable, as recommended in Chapter 16).

If you are debugging a page on multiple browsers, you can switch between the browsers and enter property references into The Evaluator on each browser and make sure all browsers return the same values. Or, you can verify that a DOM object and property are available on all browsers under test. If you are working on W3C DOM compatible browsers, invoke the `walkChildNodes()` function of The Evaluator to make sure that modifications your scripts make to the node tree are achieving the desired goals. Experiment with direct manipulation of the page's objects and node tree by invoking DOM methods as you watch the results on the page.

You should be aware of only two small cautions when you embed The Evaluator into the page. First, The Evaluator declares its own one-letter lowercase global variable names (a through z) for use in experiments. Your own code should therefore avoid one-letter global variables (but local variables, such as the `i` counter of a `for` loop, are fine provided they are initialized inside a function with a `var` keyword). Second, while embedding The Evaluator at the bottom of the page should have the least impact on the rest of your HTML and scripts, any scripts that rely on the length of the `document.forms` array will end up including the form that is part of The Evaluator. You can always quickly turn off The Evaluator by commenting out the `printEvaluator()` statement in the bottom script to test your page on its own.

The embeddable Evaluator is without question the most valuable and frequently used debugging tool in my personal arsenal. It provides x-ray vision into the object model of the page at any resting point.

Emergency evaluation

Using The Evaluator assumes that you thought ahead of time that you want to view property values of a page. But what if you haven't yet embedded The Evaluator, and you encounter a state that you'd like to check out without disturbing the currently loaded page?

To the rescue comes the `javascript: URL` and the Location/Address box in your browser's toolbar. By invoking the `alert()` method through this URL, you can view the value of any property. For example, to find out the content of the cookie for the current document, enter the following into the Location/Address box in the browser:

```
javascript: alert(document.cookie)
```

Object methods or script functions can also be invoked this way, but you must be careful to prevent return values from causing the current page to be eliminated. If the method or function is known to return a value, you can display that value in an alert dialog box. The syntax for a function call is:

```
javascript:alert(myFunction("myParam1"))
```

And if you want to invoke a function that does not necessarily return a value, you should also protect the current page by using the void operator, as follows:

```
javascript:void myFunction("myParam1")
```

A Simple Trace Utility

Single-stepping through running code with a JavaScript debugger is a valuable aid when you know where the problem is. But when the bug location eludes you, especially in a complex script, you may find it more efficient to follow a rapid trace of execution and viewing intermediate values along the way. The kinds of questions that this debugging technique addresses include:

- ♦ How many times is that loop executing?
- ♦ What are the values being retrieved each time through the loop?
- ♦ Why won't the while loop exit?
- ♦ Are comparison operators behaving as I'd planned in `if...else` constructions?
- ♦ What kind of value is a function returning?

A bonus feature of the embeddable Evaluator is a simple trace utility that lets you control where in your running code values can be recorded for viewing after the scripts run. The resulting report you get after running your script can answer questions like these and many more.

The `trace()` function

Listing 45-1 shows the `trace()` function that is built into the `evaluator.js` library file. By embedding the Evaluator into your page under construction, you can invoke the `trace()` function wherever you want to capture an interim value.

Listing 45-1: `trace()` function

```
function trace(flag, label, value) {
  if (flag) {
    var msg = ""
    if (trace.caller) {
      var funcName = trace.caller.toString()
      funcName = funcName.substring(9, funcName.indexOf("(") + 1)
      msg += "In " + funcName + ": "
    }
    msg += label + "=" + value + "\n"
    document.forms["ev_evaluator"].ev_output.value += msg
  }
}
```

The `trace()` function takes three parameters. The first, `flag`, is a Boolean value that determines whether the trace should proceed (I show you a shortcut for setting this flag later). The second parameter is a string used as a plain-language way for you to identify the value being traced. The value to be displayed is passed as the third parameter. Virtually any type of value or expression can be passed as the third parameter — which is precisely what you want in a debugging aid.

Only if the flag parameter is `true` does the bulk of the `trace()` function execute. The first task is to extract the name of the function from which the `trace()` function was called. Unfortunately, the `caller` property of a function is missing from NN6 (and ECMAScript), so this information is made part of the result only if the browser running the trace supports the property. By retrieving the rarely used `caller` property of a function, the script grabs a string copy of the entire function that has just called `trace()`. A quick extraction of a substring from the first line yields the name of the function. That information becomes part of the message text that records each trace. The message identifies the calling function followed by a colon; after that comes the label text passed as the second parameter plus an equals sign and the value parameter. The format of the output message adheres to the following syntax:

```
In <funcName>: <label>=<value>
```

The results of the trace — one line of output per invocation — are appended to the Results textarea in The Evaluator. It's a good idea to clear the textarea before running a script that has calls to `trace()` so that you can get a clean listing.

Preparing documents for `trace.js`

As you build your document and its scripts, you need to decide how granular you want tracing to be: global or function-by-function. This decision affects at what level you place the Boolean “switch” that turns tracing on and off.

You can place one such switch as the first statement in the first script of the page. For example, specify a clearly named variable and assign either `false` or zero to it so that its initial setting is off:

```
var TRACE = 0
```

To turn debugging on at a later time, simply edit the value assigned to `TRACE` from zero to one:

```
var TRACE = 1
```

Be sure to reload the page each time you edit this global value.

Alternatively, you can define a local `TRACE` Boolean variable in each function for which you intend to employ tracing. One advantage of using function-specific tracing is that the list of items to appear in the Results textarea will be limited to those of immediate interest to you, rather than all tracing calls throughout the document. You can turn each function's tracing facility on and off by editing the values assigned to the local `TRACE` variables.

Invoking trace()

All that's left now is to insert the one-line calls to `trace()` according to the following syntax:

```
trace(TRACE, <"label">, <value>)
```

By passing the current value of `TRACE` as a parameter, you let the library function handle the decision to accumulate and display the trace. The impact on your running code is kept to a one-line statement that is easy to remember. To demonstrate how to make the calls to `trace()`, Listing 45-2 shows a pair of related functions that convert a time in milliseconds to the string format "hh:mm". To help verify that values are being massaged correctly, the script inserts a few calls to `trace()`.

Listing 45-2: Calling trace()

```
function timeToString(input) {
  var TRACE = 1
  trace(TRACE, "input", input)
  var rawTime = new Date(eval(input))
  trace(TRACE, "rawTime", rawTime)
  var hrs = twoDigitString(rawTime.getHours())
  var mins = twoDigitString(rawTime.getMinutes())
  trace(TRACE, "result", hrs + ":" + mins)
  return hrs + ":" + mins
}

function twoDigitString(val) {
  var TRACE = 1
  trace(TRACE, "val", val)
  return (val < 10) ? "0" + val : "" + val
}
```

After running the script, the Results box in The Evaluator shows the following trace:

```
In timeToString(input): input=976767964655
In timeToString(input): rawTime=Wed Dec 13 20:26:04 GMT-0800 2000
In twoDigitString(val): val=20
In twoDigitString(val): val=26
In timeToString(input): result=20:26
```

Having the name of the function in the trace is helpful in cases in which you might justifiably reuse variable names (for example, `i` loop counters). You can also see more clearly when one function in your script calls another.

One of the most valuable applications of the `trace()` function comes when your scripts accumulate HTML that gets written to other windows or frames, or replaces HTML segments of the current page. Because the source view may not display the precise HTML that you assembled, you can output it via the `trace()` function to the Results box. From there, you can copy the HTML and paste it into a fresh document to test in the browser by itself. You can also verify that the HTML content is being formatted the way that you want it.

Browser Crashes

Each new browser generation is less crash-prone than its predecessor, which is obviously good news for everyone. It seems that most crashes, if they occur, do so as the page loads. This can be the result of some ill-advised HTML, or something happening as the result of script statements that either run immediately as the page loads or in response to the `onLoad` event handler.

Finding the root of a crash problem is perhaps more time consuming because you must relaunch the browser each time (and in some cases, even reboot your computer). But the basic tactics are the same. Reduce the page's content to the barest minimum HTML by commenting out both scripts and all but HEAD and BODY tags. Then begin enabling small chunks to test reloading of the page. Be suspicious of META tags inserted by authoring tools. Their removal can sometimes clear up all crash problems. Eventually you will add something into the mix that will cause the crash. It means that you are close to finding the culprit.

Preventing Problems

Even with help of authoring and debugging tools, you probably want to avoid errors in the first place. I offer a number of suggestions that can help in this regard.

Getting structure right

Early problems in developing a page with scripts tend to be structural: knowing that your objects are displayed correctly on the page; making sure that your `<SCRIPT>` tags are complete; completing brace, parenthesis, and quoted pairs. I start writing my page by first getting down the HTML parts — including all form definitions. Because so much of a scripted page tends to rely on the placement and naming of interface elements, you will find it much easier to work with these items after you lay them out on the page. At that point, you can start filling in the JavaScript.

When you begin defining a function, repeat loop, or `if` construction, fill out the entire structure before entering any details. For example, when I define a function named `verifyData()`, I enter the entire structure for it:

```
function verifyData() {  
  
}
```

I leave a blank line between the beginning of the function and the closing brace in anticipation of entering at least one line of code.

After I decide on a parameter to be passed and assign a variable to it, I may want to insert an `if` construction. Again, I fill in the basic structure:

```
function verifyData(form) {  
    if (form.checkbox.checked) {  
  
    }  
}
```

This method automatically pushes the closing brace of the function lower, which is what I want — putting it securely at the end of the function where it belongs. It also ensures that I line up the closing brace of the `if` statement with that grouping. Additional statements in the `if` construction push down the two closing braces.

If you don't like typing or don't trust yourself to maintain this kind of discipline when you're in a hurry to test an idea, you should prepare a separate document that has templates for the common constructions: `<SCRIPT>` tags, `function`, `if`, `if...else`, `for` loop, `while` loop, and conditional expressions. Then if your editor and operating system support it, drag and drop the necessary segments into your working script.

Build incrementally

The worst development tactic you can follow is to write tons of code before trying any of it. Error messages may point to so many lines away from the source of the problem that it could take hours to find the true source of difficulty. The save-switch-reload sequence is not painful, so the better strategy is to try your code every time you have written a complete thought — or even enough to test an intermediate result in an alert dialog box — to make sure that you're on the right track.

Test expression evaluation

Especially while you are learning the ins and outs of JavaScript, you may feel unsure about the results that a particular string, math, or date method yields on a value. The longer your scripted document gets, the more difficult it will be to test the evaluation of a statement. You're better off trying the expression in a more controlled, isolated environment, such as The Evaluator. By doing this kind of testing in the browser, you save a great deal of time experimenting by going back and forth between the source document and the browser.

Build function workbenches

A similar situation exists for building and testing functions, especially generalizable ones. Rather than test a function inside a complex scripted document, drop it into a skeletal document that contains the minimum number of user interface elements that you need to test the function. This task gets difficult when the function is closely tied to numerous objects in the real document, but it works wonders for making you think about generalizing functions for possible use in the future. Display the output of the function in a text or textarea object or include it in an alert dialog box.

Testing Your Masterpiece

If your background strictly involves designing HTML pages, you probably think of testing as determining your user's ability to navigate successfully around your site. But a JavaScript-enhanced page — especially if the user enters input into fields or implements Dynamic HTML techniques — requires a substantially greater amount of testing before you unleash it to the online masses.

A large part of good programming is anticipating what a user can do at any point and then being sure that your code covers that eventuality. With multiframe windows, for example, you need to see how unexpected reloading of a document affects the relationships between all the frames — especially if they depend on each other. Users will be able to click Reload at any time or suspend document loading in the middle of a download from the server. How do these activities affect your scripting? Do they cause script errors based on your current script organization?

The minute you enable a user to type an entry into a form, you also invite the user to enter the wrong kind of information into that form. If your script expects only a numeric value from a field, and the user (accidentally or intentionally) types a letter, is your script ready to handle that “bad” data? Or no data? Or a negative floating-point number?

Just because you, as author of the page, know the “proper” sequence to follow and the “right” kind of data to enter into forms, your users will not necessarily follow your instructions. In days gone by, such mistakes were relegated to “user error.” Today, with an increasingly consumer-oriented Web audience, any such faults rest solely on the programmer — you.

If I sound as though I’m trying to scare you, I have succeeded. I was serious in the early chapters of this book when I said that writing JavaScript is *programming*. Users of your pages are expecting the same polish and smooth operation (no script errors and certainly no crashes) from your site as from the most professional software publisher on the planet. Don’t let them or yourself down. Test your pages extensively on as many browsers and as many operating systems as you can and with as wide an audience as possible before putting the pages on the server for all to see.

Security and Netscape Signed Scripts

The paranoia levels about potential threats to security and privacy on the Internet are at an all-time high. As more people rely on e-mail and Web site content for their daily lives and transactions, the fears will only increase for the foreseeable future (an indeterminate number of Web Weeks). As a jokester might say, though, “I may be paranoid, but how do I know someone really isn’t out to get me?” The answer to that question is that you don’t know, and such a person may be out there.

But Web software developers are doing their darnedest to put up roadblocks to those persons out to get you—hence, the many levels of security that pervade browsers. Unfortunately, these roadblocks also get in the way of scripters who have completely honest intentions. Designing a Web site around these barriers is one of the greatest challenges that many scripters face.

Battening Down the Hatches

When Navigator 2 first shipped to the world (way back in February 1996), it was the first browser released to include support for Java applets and scripting—two entirely different but often confused technologies. It didn’t take long for clever programmers in the Internet community to find the ways in which one or the other technology provided inadvertent access to client computer information (such as reading file directories) and Web surfer activities (such as histories of where you’ve been on the Net and even the passwords you may have entered to access secure sites).

JavaScript, in particular, was the avenue that many of these programmers used to steal such information from Web site visitors’ browsers. The sad part is that the same features that provide the access to the information were intentionally made a part of the initial language to aid scripters who would put

46

CHAPTER

In This Chapter

Exploring browser security policies

Applying JavaScript to Navigator security mechanisms

Using Netscape signed scripts

those features to beneficial use in controlled environments, such as intranets. But out in the Wild Wide Web, a scripter could capture a visitor's e-mail address by having the site's home page surreptitiously send a message to the site's author without the visitor even knowing it.

Word of security breaches of this magnitude not only circulated throughout the Internet, but also reached both the trade and mainstream press. As if the security issues weren't bad enough on their own, the public relations nightmare compounded the sense of urgency to fix the problem. To that end, Netscape released two revised editions of Navigator 2. The final release of that generation of browser, Navigator 2.02, took care of the scriptable security issues by turning off some of the scripted capabilities that had been put into the original 2.0 version. No more capturing visitors' browser histories; no more local file directory listings; no more silent e-mail. Users could even turn off JavaScript support entirely if they so desired.

The bottom line on security is that scripts are prevented from performing automated processes that invade the private property of a Web author's page or a client's browser. Thus, any action that may be suspect, such as sending an e-mail message, requires an explicit action on the part of the user—clicking a Submit button, in this case—to carry it out. Security restrictions must also prevent a Web site from tracking your activity beyond the boundaries of that Web site.

When Worlds Collide

If a script tries to do something that is not allowed or is a potential personal security breach, the browser reports the situation to the user. Figure 46-1, for instance, shows an IE/Windows warning a user gets from clicking a Submit button located in a form whose ACTION is set to a `mailto:` URL.

Another security error message often confuses scripters who don't understand the possible privacy invasions that can accrue from one window or frame having access to the URL information in another window or frame. In IE5/Windows, for example, an ominous error message—"Permission denied"—warns users of an attempt to access URL information from another frame if that URL is from a different Web site.

Despite the fact that a scripted Web site may have even loaded the foreign URL into the other frame, the security restrictions guard against unscrupulous usage of the ability to snoop in other windows and frames.

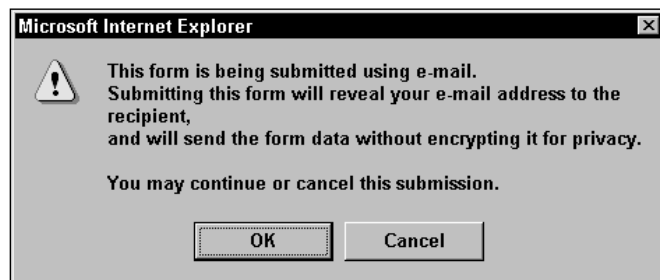

Figure 46-1: IE/Windows e-mail warning

The Java Sandbox

Much of the security model for JavaScript is similar to that originally defined for Java applets. Applets had a potentially dangerous facility of executing Java code on the client machine. That is a far cry from the original deployment of the World Wide Web as a read-only publishing medium on the Internet. Here were mini-programs downloaded into a client computer that, if unchecked, could have the same access to the system as a local software program.

Access of this type would clearly be unacceptable. Imagine the dismay caused by someone clicking a link that said “Free Money,” only to have the linked page download an applet that read or damaged local disk files unbeknownst to the user. In anticipation of pranksters, the designers of Java and the Java virtual machine built in a number of safeguards to prevent applets from gaining access to local machines. This mechanism is collectively referred to as the sandbox, a restricted area in which applets can operate. Applets cannot extend their reach outside of the sandbox to access local file systems and many sensitive system preferences. Any applet runs only while its containing page is still loaded in the browser. When the page goes away, so does the applet, without being saved to the local disk cache.

JavaScript adopted similar restrictions. The language provided no read or write access to local files beyond the highly regulated cookie file. Moreover, because JavaScript works more closely with the browser and its documents than applets typically do, the language had to build in extra restrictions to prevent browser-specific privacy invasions. For example, it was not possible for a script in one window to monitor the user’s activity in another window, including the URL of the other window, if the page didn’t come from the same server as the first window. Sometimes the restrictions on the JavaScript side are even more severe than in Java. For example, while a Java applet is permitted to access the network anytime after the applet is loaded, an applet is prevented from reaching out to the Net if the trigger for that transaction comes from JavaScript via LiveConnect (see Chapter 44). Only partial workarounds are available.

Neither the Java nor JavaScript security blankets were fully bug-free at the outset. Some holes were uncovered by the languages’ creators and others in the community. To their credit, Sun and Netscape (and Microsoft for that matter) are quick to plug any holes that are discovered. While the plugs don’t necessarily fix existing copies of insecure browsers out there, it means that a Bad Guy can’t count on every browser to offer the same security hole for exploitation. That generally makes the effort not worth the bother.

Security Policies

Netscape describes security mechanisms under the collective term *policies*. This usage of the word mirrors that of institutions and governments: A policy defines the way potentially insecure or invasive requests are handled by the browser or scripting language. NN4+ includes two different security policies: *same origin* and *signed script* policies. The same origin policy dates back to Navigator 2, although some additional rules have been added to that policy as Navigator has matured. The signed script policy started with NN4 and utilizes the state of the art in cryptographic signatures of executable code inside a browser, whether that code is a

plug-in, a Java applet, or a JavaScript script. Because of the signed script facilities, NN4+ was designed to allow scripts to have wider range of control over the browser's interior working parts, provided the user granted permission for such activity (more about this later in the chapter). NN3 included a partially implemented prototype of another policy known as data tainting. Signed scripts supersede data tainting, so if you encounter any writings about data tainting, you can ignore them because the technology is not being further developed.

By and large, the same origin policy is in force inside IE3 and after. Precise details may not match up with NN one-for-one, but the most common features are identical. The signed script policy is implemented only in NN4+. While Microsoft offers digital signatures for some items that may be embedded within an HTML page (such as ActiveX controls and other components), scripts that are in an HTML page's source code or linked in as a `.js` library cannot be signed for IE. While everything you read in this chapter about signed scripts applies only to NN4+, you should find the next couple of sections informative even if you develop solely for IE.

The Same Origin Policy

The “origin” of the same origin policy means the protocol and domain of a source document. If all of the source files currently loaded in the browser come from the same server and domain, scripts in any one part of the environment can poke around the other documents. Restrictions come into play when the script doing the poking and the document being poked come from different origins. The potential security and privacy breaches this kind of access can cause put this access out of bounds within the same origin policy.

An origin is not the complete URL of a document. Consider the two popular URLs for Netscape's Web sites:

```
http://home.netscape.com
http://developer.netscape.com
```

The protocol for both sites is `http:`. Both sites also share the same domain name: `netscape.com`. But the sites run on two different servers: `home` and `developer` (at least this is how the sites appear to browsers accessing them; the physical server arrangement may be quite different).

If a frameset contains documents from the same server at `netscape.com`, and all frames are using the same protocol, then they have the same origin. Completely open and free access to information, such as `location` object properties, is available to scripts in any frame's document. But if one of those frames contains a document from the other server, their origins don't match. A script in a document from one server would display an “access disallowed” or “permission denied” error message if it tried to get the `location` property of that other document.

A similar problem occurs if you were creating a Web-based shopping service that displays the product catalog in one window and displays the order form from a secure server in another window. The order form, whose protocol might be `https:`, would not be granted access to the `location` object properties in a catalog page whose protocol is `http:`, even though both share the same server and domain name.

Setting the `document.domain`

When both pages in an origin-protected transaction are from the same domain (but different servers or protocols), you can instruct JavaScript to set the `document.domain` properties of both pages to the domain that they share. When this property is set to that domain, the pages are treated as if from the same origin. Making this adjustment is safe, because JavaScript doesn't allow setting the `document.domain` property to any domain other than the origin of the document making the setting. See the `document.domain` property entry in Chapter 18 for further details.

Origin checks

Scattered throughout the language reference chapters are notes about items that undergo what you now know to be *origin checks*. For the sake of convenience, I list them all here to help you get a better feeling for the kind of information that is protected. The general rule is that any object property or method that exposes a local file in a user's system or can trace Web surfing activity in another window or frame undergoes an origin check. Failure to satisfy the same origin rule yields an "access disallowed" or "permission denied" error message on the client's machine.

Window object checks

The document object models of windows and frames that don't share the same origin are not available to each other. Each separate origin window or frame is its own little world that has very little ability to communicate with another window or frame. IE sometimes takes this to the extreme, causing problems between a main window and a subwindow whose content is entirely dynamically generated from the main window's scripts.

Location object checks

All `location` object properties are restricted to same origin access. Of all same origin policy restrictions, this one seems to interfere with well-meaning page authors' plans when they want to provide a frame for users to navigate around the Web. Such access, however, would allow spying on your users.

Document object checks

A document object's properties are by necessity loaded with information about the content of that document. Just about every property other than the ones that specify color properties are off-limits if the origin of the target document is different from the one making the request:

<code>anchors[]</code>	<code>lastModified</code>
<code>applets[]</code>	<code>length</code>
<code>cookie</code>	<code>links[]</code>
<code>domain</code>	<code>referrer</code>
<code>embeds</code>	<code>title</code>
<code>forms[]</code>	<code>URL</code>

In addition, no normally modifiable document property can be modified if the origin check fails. This, of course, does not prevent you from using `document.write()` to write an entirely new page of content to the frame to replace

a document from a different origin. But in IE4+ and W3C DOM browsers, scripts from one origin won't be able to modify (or even copy) partial content from a frame whose content comes from another origin.

NN4 layer object checks

While most of a NN4 layer's content is protected by the restrictions that apply to the `document` object inside, a layer object also has a potentially revealing `src` property. This is essentially similar to the `location.href` property of a frame. Thus the `src` property requires an origin check before yielding its information.

Form object checks

Form data is generally protected by the restriction to a document's `forms[]` array. But should a script in another window or frame also know the name of the form, that, too, won't enable access unless both documents come from the same origin.

Applet object checks

The same goes for named Java applets. A script cannot retrieve information about the class file name unless both documents are from the same origin (although the applet can be from anywhere).

LiveConnect access from a Java applet to JavaScript is not an avenue to other windows and frames from other origins. Any calls from the applet to the objects and protected properties described here undergo origin checks when those objects are in other frames and windows. The applet assumes the origin of the document that contains the applet, not the applet codebase.

Image object checks

While image objects are accessible from other origins, their `src` and `lowsrc` properties are not. These URLs could reveal some or all the URL info about the document containing them.

Linked script library checks

To prevent a network-based script from hijacking a local script library file, NN4+ prevents a page from loading a `file:` protocol library in the `SRC` attribute of a `<SCRIPT>` tag unless the main document also comes from a `file:` protocol source. If you are beginning to think that security engineers are a suspicious and paranoid lot, you are starting to get the idea. It's not easy to curb potential abuses of Bad Guys in a networked environment initially established for openness and free exchange of information among trusted individuals.

The Netscape Signed Script Policy

Just as there are excellent reasons to keep Web pages from poking around your computer and browser, there are equally good reasons to allow such access to a Web site you trust not to be a Bad Guy. To permit trusted access to the client machine and browser, Sun Microsystems and Netscape (in cooperation with other sources) have developed a way for Web application authors to identify themselves officially as authors of the pages and to request permission of the user to access well-defined parts of the computer system and browser.

The technology is called object *signing*. In broad terms, object signing means that an author can electronically lock down a chunk of computer code (whether it

be a Java applet, a plug-in, or a script) with the electronic equivalent of a wax seal stamped by the author's signet ring. At the receiving end, a user is informed that a sealed chunk of code is requesting some normally protected access to the computer or browser. The user can examine the "seal" to see who authored the code and the nature of access being requested. If the user trusts the author not to be a Bad Guy, the user grants permission for that code to execute; otherwise the code does not run at all. Additional checks take place before the code actually runs. That electronic "seal" contains an encrypted, reduced representation of the code as it was locked by the author. If the encrypted representation cannot be re-created at the client end (it takes only a fraction of a second to check), it means the code has been modified in transit and will not run.

In truth, nothing prevents an author from being a Bad Guy, including someone you may normally trust. The point of the object signing system, however, is that a trail leads back to the Bad Guy. An author cannot use this technology to sneak into your computer or browser without your explicit knowledge and permission.

Signed objects and scripts

A special version of the signed object technology is the one that lets scripts be locked down by their author and electronically signed. Virtually any kind of script in a document can be signed: a linked `.js` library, scripts in the document, event handlers, and JavaScript entities. As described later in this chapter, you must prepare your scripts for being signed, and then run the entire page through a special tool that attaches your electronic signature to the scripts within that page.

What you get with signed scripts

If you sign your scripts and the user grants your page permission to do its job, signed scripts open up your application to a long list of capabilities, some of which border on acting like genuine local applications. Because the designers of NN4+ know that signed scripts are available to authors, a huge number of properties and actions are exposed to authors.

The most obvious power you get with signed scripts is freedom from the restrictions of the same origin policy. All object properties and methods that perform origin checks for access in other frames and windows become available to your scripts without any special interaction with the user beyond the dialog box that requests the one-time permission for the page.

Some operations that normally display warnings about impending actions — sending a form to a `mailto:` URL or closing the main browser window under script control — lose those warning dialog boxes if the user grants the appropriate permission to a signed script. Object properties considered private information, such as individual URLs stored in the history object and browser preferences, are opened up, including the possibility of altering browser preferences. Existing windows can have their chrome elements hidden. New windows can be set to be always raised or lowered, sized to very small sizes, or positioned offscreen. The `dragDrop` event of a window reveals its URL. All of these are powerful points of access, provided the user grants permission.

Again, however, I emphasize that these capabilities are accessible via Netscape's signed script policy only. Internet Explorer, at least through Version 5.5, does not support Netscape's signed script policy.

The Digital Certificate

Before you can sign a script or other object, you must apply for a digital certificate. A digital certificate (also called a digital ID) is a small piece of software that gets downloaded and bound to the developer's Navigator browser on a particular computer. Each downloaded digital certificate appears in the list of certificates under the "Mine" category in Navigator 6's Security Manager window (accessible through the Tasks menu). If you have not yet applied for a certificate, the list is empty. When you sign a page with the certificate, information about the certificate is included in the file generated by the signing tool.

Possession of a certificate makes you what is known as a principal. If a user loads a page that has signed "stuff" in it, a security alert advises the user that a Web site is requesting enhanced privileges.

Certificates are issued by organizations established as certificate authorities. A certificate authority (known as a CA for short), or a certificate server authorized by a CA, registers applicants and issues certificates to individuals and software developers. When you register for a certificate, the CA queries you for identification information, which it verifies as best it can. The certificate that is issued to you identifies you as the holder of the certificate. Under the "Authorities" category of the Security Manager window are the certificate authorities loaded into the browser when you installed the browser. These are organizations that issue certificates. The CA of the organization that issues your certificate must be listed for you to sign scripts.

How to get a certificate

You must visit a certificate vendor to obtain your certificate. The cost ranges from about \$20 to many hundreds of dollars depending on the vendor and the type of certificate you want to obtain. One vendor that is aware of the needs of Netscape object signing is Thawte Digital Certificate Services (www.thawte.com). This CA offers a certificate expressly for developers performing Netscape object signing. Verisign (www.verisign.com) is also recommended.

Because one of the foundations of a certificate is the identity of the certificate owner, registration requires submitting documentation that proves the identity of your organization. Each CA has different requirements, so check the latest information at the CA's enrollment Web site. After the CA processes your application, the company sends you an e-mail message with a code number to pick up your certificate at the CA's Web site. The act of picking up the certificate is actually downloading the certificate into your browser. Therefore, be sure you are using the Navigator browser on the computer with which you will use to sign your pages.

Activating the codebase principal

If you want to try out the capabilities available to signed scripts from a server without purchasing a certificate (or without going through the signing process described later in this chapter during script development and debugging), you can set up your copy of Navigator to accept what is called a *codebase principal* in place of a genuine certificate. A codebase principal means that the browser accepts the source file as a legitimate principal, although it contains no identification as to the owner or certificate.

Depending on which version of Navigator you are running, if you set up your browser for codebase principals, you may not be able to verify a certificate that is presented to you when accessing someone else's Web site — even if it is a valid cryptographic certificate. Therefore, even though secure requests won't slip past you silently, your Navigator won't necessarily have the protective shield it normally does to identify certificate holders beyond the URL of the code. Enable codebase principals only on a copy of Navigator that doesn't venture beyond your development environment. To activate codebase principals for your copy of Navigator, follow these steps:

1. Quit Navigator.
2. Search your hard disk for a Navigator 4 support file named `prefs.js` or Navigator 6 support file named `all.js`.
3. Edit the version-specific file in a text editor as follows:
 - a. For NN4, add the following line to the end of the `prefs.js` file:

```
user_pref("signed.applets.codebase_principal_support", true);
```
 - b. For NN6, change the `codebase_principal` preference in `all.js` from `false` to `true`:

```
pref("signed.applets.codebase_principal_support", true);
```
4. Save the file.

To deactivate codebase principals, quit Navigator and then change the `true` setting of the affected line to `false`. Because Navigator 4 rebuilds the preference file upon quitting, the entry will be in alphabetical order rather than at the end of the file where you first entered it. This preferences setting does not affect your ability to sign scripts with your certificate as described in the rest of this article.

Signing Scripts

The process of signing scripts entails some new concepts for even experienced JavaScript authors. You must use a separate signing tool program. You must also prepare the page that bears scripts so that the tool and the object signing facilities of the browser can do their jobs.

Signing tool

Download the latest version of Netscape's SignTool from links you find at <http://developer.netscape.com:80/software/signedobj/jarpack.html> (you find different versions for a variety of Windows and Unix versions). This tool includes a utility program called a JAR Packager. A JAR file is a special kind of zipped file collection that has been designed to work with the Navigator security infrastructure. The letters of the name stand for Java ARchive, which is a file format standard developed primarily by Sun Microsystems in cooperation with Netscape and others.

A JAR file's extension is `.jar`, and when it contains signed script information, it holds at least one file, known as the *manifest*, or list of items zipped together in the file. Among the items in the manifest is certificate information and data (a hash

value code) about the content of the signed items at the instant they were signed. In the case of a single page containing signed scripts, the JAR file contains only the certificate and hash values of the signed scripts within the document. If the document links in an external `.js` script library file, that library file is also packaged in the JAR file. Thus, a page with signed scripts occupies space on the server for the HTML file and its companion JAR file.

The SignTool program combines the JAR Packager with the script signing functions (originally a separate program called `zigbert.exe`). Follow links on the SignTool download page to the latest instructions on packaging and signing your finished files from the command line (there is no GUI for this tool). But before you reach that point, you need to compose your pages in a way that the security mechanism can protect your scripts.

Preparing scripts for signing

Signifying which items in a page are script items that require signing is up to the page author. It is important to remember that if you want to sign even one script element in a document, *every* script in the document must be signed. By “document,” I mean an object model document. Because the content of an NN4-only `<LAYER>` tag exists in its own document, you don’t have to sign its scripts if they don’t require it, nor communicate with the signed scripts in the main document.

The first concept you have to master is recognizing what a script is. For signing purposes, a script is more than just the set of statements between a `<SCRIPT>` and `</SCRIPT>` tag boundary. An event handler — even one that calls a function living in a `<SCRIPT>` tag — is also a script that needs signing. So, too, is a JavaScript entity used to supply a value to an HTML tag attribute. Each one of these items is a script as far as script signing is concerned.

Your job is to mark up the file with special tag attributes that do two things: 1) help SignTool know what items to sign in a file; and 2) help the browser loading the signed document know what items to run through the hash routine again to compare against the values stored in the JAR file.

The ARCHIVE attribute

The first attribute goes in the first `<SCRIPT>` tag of the file, preferably near the very top of the document in the `<HEAD>` portion. This attribute is the `ARCHIVE` attribute, and its value is the name of the JAR file to be associated with the HTML file. For example

```
<SCRIPT LANGUAGE="JavaScript" ARCHIVE="myArchive.jar" ID="1">
```

You can add script statements to this tag or immediately end it with a `</SCRIPT>` tag.

SignTool utility uses the `ARCHIVE` attribute to assign a name to its archive output file. After the signed page loads into the visitor’s browser, the attribute points to the file containing signed script information. Having more than one JAR archive file associated with a signed page is possible. Typically, such a situation calls for a second JAR archive overseeing a confined portion of the page. That second archive file may even be embedded in the primary archive file, allowing a script segment signed by one principal to be combined with scripts signed by a different principal.

The ID attribute

More perplexing to scripters coming to script signing for the first time is the ID attribute. The ID attribute is merely a label for each script. Each script must have a label that is unique among all labels specified for a JAR archive file.

As with the ARCHIVE attribute, the ID plays a dual role. When you run your page through SignTool, the utility scans the page for these ID attributes. When SignTool encounters one, it calculates a hash value (something like a checksum) on the content of the script. For a <SCRIPT> tag set, it is for the entire content of the tag set; for an event handler, it is for the event handler text. The hash value is associated with the ID attribute label and stored inside the JAR file. After the document loads into the client's browser, the browser also scans for the ID attributes and performs the same hash calculations on the script items. Then the browser can compare the ID/hash value pairs against the list in the JAR file. If they match, then the file has arrived without being modified by a Bad Guy (or a dropped bit in the network).

Most examples show ID attribute values to be numbers, but the attributes are actually strings. No sequence or relationship exists among ID attribute values: you can use the names of your favorite cartoon show characters, as long as no two ID attributes are given the same name. The only time the same ID attribute value may appear in a document is if another JAR file is embedded within the main JAR file. Even so, I recommend avoiding reusing names inside the same HTML file, no matter how many JAR files are embedded.

With one exception, each script item in a document must have its own ID attribute. The exception is a <SCRIPT> tag that specifies a SRC attribute for an external .js file. That file is part of the JAR file, so the browser knows it's a signed script.

For other <SCRIPT> tags, include the ID attribute anywhere within the opening tag, as follows:

```
<SCRIPT LANGUAGE="JavaScript" ID="3">  
    statements  
</SCRIPT>
```

For a function handler, the ID attribute comes after the event handler inside the object tag, as follows:

```
<INPUT TYPE="button" VALUE="Calculate" onClick="doCalc(this.form)" ID="bart">
```

And for a JavaScript entity, the ID attribute must be specified in an empty <SCRIPT> tag immediately before the tag that includes the entity for an attribute value, as follows:

```
<SCRIPT ID="20">  
<INPUT TYPE="text" NAME="date" VALUE=&{getToday()};>
```

Listing 46-1 shows a skeletal structure of a document that references a single JAR file and includes five signed scripts: One external .js file and four script items in the document itself. The `fetchFile()` function invokes a function imported from `access.js`. Notice that the ARCHIVE attribute appears in the very first <SCRIPT> tag in the document. This also happens to be a tag that imports an external .js file, so that no ID attribute is required. If there were no external library file for this

page, the ARCHIVE attribute would be located in the main <SCRIPT> tag, which also has the ID attribute. I arbitrarily assigned increasing numbers as the ID attribute values, but I could have used any identifiers. Notice, too, that each script has its own ID value. Just because an event handler invokes a function in a <SCRIPT> tag that has an ID value doesn't mean a relationship exists between the ID attribute values in the <SCRIPT> tag and in the event handler that invokes a function there.

Listing 46-1: Basic Signed Script Structure

```
<HTML>
<HEAD>
<TITLE>Signed Scripts Testing</TITLE>
<SCRIPT LANGUAGE="JavaScript" ARCHIVE="myArchive.jar" SRC="access.js"></SCRIPT>
<SCRIPT LANGUAGE="JavaScript" ID="1">
function fetchFile(form) {
    form.output.value = getFile()
}
function newRaisedWindow() {
    // statements for this function
}
</SCRIPT>
</HEAD>
<BODY>
A Source Code Example Only

ID="3"><P>
<INPUT TYPE="button" VALUE="New Window..." onClick="newRaisedWindow();" ID="4">
</FORM>
</BODY>
</HTML>
```

Editing and moving signed scripts

The nature of the script signing process requires that even the slightest modification you make to a signed script source code requires re-signing the page. For this reason, enabling codebase principals while you create and debug your early code is a convenient alternative.

The rigid link between the hash value of a script element at both the signing and visitor loading times means that you must exercise care when shifting an HTML file that contains signed script elements between servers of differing operating systems. Windows, UNIX, and Macintosh have different ways of treating carriage returns. If you change the representation of an HTML source file when you move the source from, say, a Windows machine to a UNIX server, then the signature may

no longer work. However, if you perform a purely binary transfer of the HTML files, every byte is the same, and the signature should work. This operating system-specific text representation affects only how files are stored on servers, not how various client platforms interpret the source code.

Accessing Protected Properties and Methods

For the browser to allow access to protected properties or methods, it must have its privileges enabled. Only the user can grant permission to enable privileges, but it is up to your code to request those privileges of the user.

Gaining privileges

NN4+ comes with some Java classes that allow signed scripts and other signed objects to display the privilege request alert windows, and then turn on the privileges if the user clicks the “OK” or “Grant” button. A lot of these classes show up in the `netscape.security` package, but scripters only work directly with one class and three of its methods:

```
netscape.security.PrivilegeManager.enablePrivilege(["targetName"])
netscape.security.PrivilegeManager.revertPrivilege(["targetName"])
netscape.security.PrivilegeManager.disablePrivilege(["targetName"])
```

The `enablePrivilege()` method is the one that displays the security alert for the user. In NN4, the specific target named as a parameter influenced the details of the security alert message; for NN6, the security alert is generic (and far less intimidating).

If the user grants the privilege, script processing continues with the next statement. But if the user denies access, then processing stops, and the `PrivilegeManager` class throws a Java exception that gets displayed as a JavaScript error message. Later in this chapter I show you how to gracefully handle the user’s denial of access.

Enabling a privilege in JavaScript is generally not as risky as enabling a Java applet. The latter can be more easily hijacked by an alien class to piggyback on the trusted applet’s privileges. Even though the likelihood of such activity taking place in JavaScript is very low, turning privileges off after the statement that requires privileges is always a good idea. Use the `revertPrivilege()` method to temporarily turn off the privilege; another statement that enables the same privilege target will go right ahead without asking the user again. Disable privileges only when the script requiring privileged access won’t be run again until the page reloads.

Specifying a target

Rather than opening blanket access to all protected capabilities in one blow, the Netscape security model defines narrow capabilities that are opened up when privileges are granted. Each set of capabilities is called a target. Netscape defines dozens of different targets, but not all of them are needed to access the kinds of methods and properties available to JavaScript. You will likely confine your targets to the nine discussed here.

Because NN4's security alerts provided (at times excruciating) detail about the nature of the privilege being requested by the Web site, targets had various risk levels and categories. These concerns are less of an issue in NN6, but they are provided here for your more complete understanding of the mechanisms beneath the Privilege Manager.

Each target has associated with it a risk level (low, medium, or high) and two plain-language descriptions about the kinds of actions the target exposes to code. This information appears in the NN4 security privilege dialog box that faces a user the first time a particular signature requests privileges. All of the targets related to scripted access are medium or high risk, because they tend to open up local hard disk files and browser settings.

Netscape has produced two categories of targets: primitive and macro. A *primitive target* is the most limited target type. It usually confines itself to either reading or writing of a particular kind of data, such as a local file or browser preference. A *macro target* usually combines two or more primitive targets into a single target to simplify the user experience when your scripts require multiple kinds of access. For example, if your script must both read and write a local file, it could request privileges for each direction, but the user would be presented with a quick succession of two similar-looking security dialog boxes. Instead, you can use a macro target that combines both reading and writing into the privilege. The user sees one security dialog box, which, in NN4, explains that the request is for both read and write access to the local hard disk.

Likely targets for scripted access include a combination of primitive and macro targets. Table 46-1 shows the most common script-related targets and the information that appears in the security dialog box.

For each call to `netscape.security.PrivilegeManager.enablePrivilege()`, you specify a single target name as a string, as in

```
netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserRead")
```

This specification allows you to enable, revert, and disable individual privileges as required in your script.

Table 46-1 Scripting-Related Privilege Targets

<i>Target Name</i>		
<i>Risk</i>	<i>Short Description</i>	<i>Long Description</i>
UniversalBrowserAccess		
High	Reading or modifying browser data	Reading or modifying browser data that may be considered private, such as a list of Web sites visited or the contents of Web forms you may have filled in. Modifications may also include creating windows that look like they belong to another program or positioning windows anywhere on the screen.

Risk	Short Description	Long Description
UniversalBrowserRead		
Medium	Reading browser data	Access to browser data that may be considered private, such as a list of Web sites visited or the contents of Web page forms you may have filled in.
UniversalBrowserWrite		
High	Modifying the browser	Modifying the browser in a potentially dangerous way, such as creating windows that may look like they belong to another program or positioning windows anywhere on the screen.
UniversalFileAccess		
High	Reading, modifying, or deleting any of your files	This form of access is typically required by a program such as a word processor or a debugger that needs to create, read, modify, or delete files on hard disks or other storage media connected to your computer.
UniversalFileRead		
High	Reading files stored in your computer	Reading any files stored on hard disks or other storage media connected to your computer.
UniversalFileWrite		
High	Modifying files stored in your computer	Modifying any files stored on hard disks or other storage media connected to your computer.
UniversalPreferencesRead		
Medium	Reading preferences settings	Access to read the current settings of your preferences.
UniversalPreferencesWrite		
High	Modifying preferences settings	Modifying the current settings of your preferences.
UniversalSendMail		
Medium	Sending e-mail messages on your behalf	

Blending Privileges into Scripts

The implementation of signed scripts in Navigator protects scripters from many of the potential hazards that Java applet and plug-in developers must watch for. The chance that a privilege enabled in a script can be hijacked by code from a Bad Guy is very small. Still, exercising safe practices in case you someday work with other kinds of signed objects is good practice.

Keep the window small

Privilege safety is predicated on limiting exposure according to two techniques. The first technique is to enable only the level of privilege required for the protected access your scripts need. For example, if your script only needs to read a normally protected document object property, then enable the `UniversalBrowserRead` target rather than the wider `UniversalBrowserAccess` macro target.

The second technique is to keep privileges enabled only as long as the scripts need them enabled. If a statement calls a function that invokes a protected property, enable the privilege for that property in the called function, not at the level of the calling statement. If a privilege is enabled inside a function, the browser automatically reverts the privilege at the end of the function. Even so, if the privilege isn't needed all the way to the end of the function, you should explicitly revert it after you are through with the privilege.

Think of the users

One other deployment concern focuses more on the user's experience with your signed page. You should recognize that the call to the `Java PrivilegeManager` class is a `LiveConnect` call from JavaScript in NN4. Because the Java virtual machine does not start up automatically when Navigator 4 does, a brief delay occurs the first time a `LiveConnect` call is made in a session (the statusbar displays "Starting Java..."). Such a delay may interrupt the user flow through your page if, for example, a click of a button needs access to a privileged property. Therefore, consider gaining permission for protected access as the page loads. Execute an `enablePrivilege()` and `revertPrivilege()` method in the very beginning. If Java isn't yet loaded into the browser, the delay is added to the other loading delays for images and the rest of the page. Thereafter, when privileges are enabled again for a specific action, neither the security dialog box nor the startup delay get in the way for the user.

Also remember that users don't care for security dialog boxes to interrupt their navigation. If your page utilizes a couple of related primitive targets, at the outset enable the macro target that encompasses those primitive targets. The user gets one security dialog box covering all potential actions in the page. Then let your script enable and revert each primitive target as needed.

Example

To demonstrate signed scripts in action, I show a page that accesses a typical target that allows the script to open an always-raised new window. No error checking occurs for the user's denial of privilege in this example. Therefore, if you experiment with this page (either with codebase principals turned on or signing them

yourself), you will see the JavaScript error that displays the Java exception. Error detection is covered later in the chapter.

Accessing a protected window property

Listing 46-2 is a small document that contains one button. The button calls a function that opens a new window with the NN-proprietary `alwaysRaised` parameter turned on. Setting `protected window.open()` parameters in NN4+ requires the `UniversalBrowserWrite` privilege target. Inside the function, the privilege is enabled only for the creation of the new window. For this simple example, I do not enable the privilege when the document loads.

Listing 46-2: Creating an `alwaysRaised` Window

```
<HTML>
<HEAD>
<TITLE>Simple Signed Script</TITLE>
<SCRIPT LANGUAGE="JavaScript" ARCHIVE="myJar.jar" ID="1">
function newRaisedWindow() {
    netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite")
    var newWindow = window.open("", "", "HEIGHT=100,WIDTH=300,alwaysRaised")
    netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserWrite")
    var newContent = "<HTML><BODY><B>It's good to be the King!</B>"
    newContent += "<FORM><CENTER><INPUT TYPE='button' VALUE='OK'"
    newContent += "onClick='self.close()'></CENTER></FORM></BODY></HTML>"
    newWindow.document.write(newContent)
    newWindow.document.close()
}
</SCRIPT>
</HEAD>
<BODY>
<B>This button generates an always-raised new window.</B>
<FORM>
<INPUT TYPE="button" VALUE="New 'Always Raised' Window"
onClick="newRaisedWindow()" ID="2">
</BODY>
</HTML>
```

Listing 46-2 has two script items that need signing: the `<SCRIPT>` tag and the event handler for the button. Also, the `ARCHIVE` attribute points to the JAR file that contains the script signature. Note that this example file is not signed, and therefore does not include a companion JAR archive on the companion CD-ROM.

Handling Privilege Manager Errors

The change between the ways NN4 and NN6 allows scripts to intercept errors causes no small problem if you need to serve both browser versions. The primary reason you want to handle errors is that when a user denies access to advanced privileges, the `PrivilegeManager` generates an error. While the error is not destructive in any way, and it appears only in the JavaScript Console window (NN4.5+), accounting for such factors is good coding practice. Unfortunately, the

mechanism that works for NN4 doesn't work in NN6; the mechanism that works in NN6 cannot even be placed in a page that loads into NN4 without generating syntax errors. The bottom line is that you need to serve up different pages for NN4 and NN6 until such time as the NN4 installed base drops away.

For NN4, you can define an `onerror()` function that looks for the specific error message thrown by the `PrivilegeManager` class through `LiveConnect`. That function looks as the following:

```
function onerror(msg, URL, lineNum) {
    var errorMsg = msg
    if (msg.indexOf("ForbiddenTargetException") != -1) {
        errorMsg = "You have elected not to grant privileges to this script."
    }
    alert(errorMsg)
    return true
}
```

Of course, you don't have to display any message, but it may be a good place to advise users about what they're missing by not granting privilege.

For NN6, you can use the native `try...catch` exception handling, which means that the calls to the `enablePrivilege()` method of the `PrivilegeManager` class must be wrapped inside a `try` block. The function from Listing 46-2 is modified as follows:

```
function newRaisedWindow() {
    try {
        netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite")
    }
    catch(err) {
        alert("You have elected not to grant privileges to this script.")
        return
    }
    var newWindow = window.open("", "", "HEIGHT=100,WIDTH=300,alwaysRaised")
    netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserWrite")
    var newContent = "<HTML><BODY><B>It's good to be the King!</B>"
    newContent += "<FORM><CENTER><INPUT TYPE='button' VALUE='OK'"
    newContent += "onClick='self.close()></CENTER></FORM></BODY></HTML>"
    newWindow.document.write(newContent)
    newWindow.document.close()
    return
}
```

Signed Script Miscellany

In this last section of the chapter, I list some of the more esoteric issues surrounding signed scripts. Three in particular are: 1) how to allow unsigned scripts in other frames, windows, or layers to access signed scripts; 2) how to make sure your signed scripts are not stolen and reused; and 3) special notes about international text characters.

Exporting and importing signed scripts

JavaScript provides an escape route that lets you intentionally expose functions from signed scripts for access by unsigned pages. If such a function contains a trusted privilege without careful controls on how that privilege is used, a page that is not as well intentioned as yours could hijack the trust.

The command for exposing this function is `export`. The following example exports a function named `fileAccess()`:

```
export fileAccess
```

A script in another window, frame, or layer can use the `import` command to bring that function into its own set of scripts:

```
import fileAccess
```

Even though the function is now also a part of the second document, it executes within the context of the original document, whose signed script governs the privilege. For example, if you exported a function that did nothing but enable a file access privilege, a Bad Guy who studies your source code could write a page that imports that function into a page that now has unbridled file access.

If you wish to share functions from signed scripts in unsigned pages loaded into your own frames or layers, avoid exporting functions that enable privileges. Other kinds of functions, if hijacked, can't do the same kind of damage as a privileged function can.

Locking down your signed pages

Speaking of hijacking scripts, it would normally be possible for someone to download your HTML and JAR archive files and copy them to another site. When a visitor comes to that other site and loads your copied page and JAR file, your signature is still attached to the scripts. While this may sound good from a copyright point of view, you may not want your signature to appear as coming from someone else's Web server. You can, however, employ a quick trick to ensure that your signed scripts work only on your server. By embedding the domain of the document in the code, you can branch execution so that scripts work only if the file comes from your server.

The following script segment demonstrates one way to employ this technique:

```
<SCRIPT LANGUAGE="JavaScript1.2" ARCHIVE="myPage.jar" ID="1">  
if (document.URL.match(/^http:\\\\www.myDomain.com\\/\\/)) {  
    privileges statements execute only from my server  
}  
</SCRIPT>
```

This technique works only if you specify JavaScript 1.2 as the script language. Even though this branching code is visible in the HTML file, the hash value of your code is saved and signed in the archive. If someone modifies the HTML, the hash value that is recalculated when a visitor loads the page won't match the JAR file manifest, and the script signature fails.

International characters

While international characters are fine for HTML content, they should not be used in signed scripts. The problem is that international characters are often converted to other character sets for display. This conversion invalidates the signature, because the signed and recalculated hash values don't match. Therefore, do not put international characters in any signable script item. If you must include such a character, you can escape it or, in NN4, put such scripts in unsigned layers.

CHAPTER

Cross-Browser Dynamic HTML Issues

Level 4 browsers and later — NN4+ and IE4+ — were the first browsers to include World Wide Web technologies that gave page authors far more control over the display and interactive behavior of Web page content. Lumped together under the heading of Dynamic HTML (DHTML), these technologies dramatically extended the simple formatting of standard HTML that page authors had used for years. These days, scripters and designers coming to Web development for the first time take DHTML capabilities for granted; they are probably unaware that plain ol' HTML is little more than a specification to format static text and images on a page.

A lot of what the user gets with DHTML had previously been accomplished only via Java applets and plug-ins, such as Shockwave. Not that DHTML eliminates these technologies from the Web author's arsenal (DHTML doesn't do sound or video, for example), but because DHTML can accomplish much more of what authors look for in assembling page content and layout without the long downloads of applets or plug-in content, it becomes an attractive way for nonprogrammers to spice up Web applications.

Perhaps categorizing DHTML authors as “nonprogrammers” is not quite right. DHTML also adds significantly to the vocabulary required to incorporate dynamic content into pages. Suddenly HTML becomes a lot more programming than simply adding tags to existing content. And if you want to do dynamic positioning of elements, be prepared to put your JavaScript skills to use.

What Is DHTML?

You can practically find as many definitions of Dynamic HTML as there are people to ask. This is especially true if you ask Netscape and Microsoft. Each company defines DHTML in

In This Chapter

Introducing Dynamic HTML

The common denominator of DHTML functionality across browsers

Upgrading to modern compatibility techniques

terms of the support its browser has for a variety of technologies. My definition covers a broad range, because DHTML is not really any one “thing.” Instead it is an amalgam of several technologies, each of which has a standards effort in varying stages of readiness. The key technologies are as follows: Cascading Style Sheets; Document Object Model (DOM); and client-side scripting. To this list I also admit recent advances in Extensible Markup Language (XML), which opens the door to author-generated, page-specific HTML extensions that don’t rely on standards bodies or browser support. It will help your authoring skills if you have a little historical perspective on how the Web arrived at DHTML.

For many years, the HTML standard was intended for the rendering of static content — not much more than an electronic version of a printed page. The most interactive part of a page was a form, which included buttons to click and text boxes to fill in. But for anything to change on the page, the content had to be served up again from the host computer.

Client-side scripting, as first implemented through JavaScript in NN2, opened the way for HTML pages to not only contain some “smarts,” but also control individual pieces of content on the page without fetching a modified page from the server. At first, only form elements were scriptable. Soon thereafter, images could be swapped, although the rectangular space for the image was fixed when the page loaded. More dynamism accrued to pages in NN4 by way of the layer, which acted like a borderless, transparent or opaque window that could contain its own HTML document content and be positioned anywhere on the page, including overlapping content on the main page or other layers. A layer’s entire content could be modified without touching the rest of the page or other layers.

But the real breakthrough in dynamism came in IE4, whose rendering engine permitted any element to be modified, inserted, or removed on the fly, while the rest of the page reflowed its content quickly and automatically in response to the change. At the same time, an accepted standard for style sheets (Cascading Style Sheets) opened the way for scripts to modify the look of content already on the page. Text could change colors when a cursor rolled atop it by either adjusting the style sheet property associated with the text or changing the style sheet rule that applies to the text.

Development activity at both Netscape and Microsoft eventually led to a standard for the Document Object Model as a way for scripts to control HTML content directly. Unfortunately, the browser makers frequently implemented first, and then tried to establish their implementations as standards. Sometimes the implementations were not as complete as the standards became, leaving the browsers in states that only partially implement the standards, while paying homage to legacy implementations. Netscape used the occasion of developing an entirely new code base for what became NN6 to try to sever some ties with the past. In many respects that browser represents the state of the standard art as implemented so far. Newest versions of IE, on the other hand, must try to cater to both the legacy implementation and the standards, creating a massive DOM implementation with significant overlap in functionality with different syntaxes. Thus, the result of proprietary explorations and industry standards is a choice of modern browsers that permit a wide range of dynamic activity on content that reaches the browser. Browsers that had started life as sleepy renderers of a tiny HTML vocabulary have grown into powerful front ends for server applications, if not self-contained applications of a sort that execute entirely on the client computer.

Standards for CSS, DOM, and ECMA scripting have been well covered earlier in this book. The purpose of this chapter is to demonstrate approaches to accommodating the sometimes vast differences in specific implementations of these technologies (including browser-specific variations) to produce content that runs on as many DHTML-capable browsers as possible. Most of the problems, as you are well aware from Chapters 15 and 31, are caused by page authors trying to develop for essentially three different document object models: NN4, IE4+, and W3C DOM (as implemented in IE5+ and NN6).

Striving for Compatibility

With as many as three object models to support (you can, of course, elect to support only a subset of browsers if you like) you should look for ways to minimize your pain. If the NN4 object model is in your mix, you will very likely experience moments of sheer torture, as you try to get even the CSS-supported HTML to behave as it does in browsers of the other object models. Thankfully, the NN4 browser's installed base is shrinking, but for some page authors, it can't disappear quickly enough.

Two keys to survival are among the object models: knowing each DOM's limitations and finding common denominators.

In the area of DHTML limitations, NN4 is the clear winner. Compared to the automatic content reflowing of IE4+ and NN6, the NN4 object model is painfully static. For example, dynamically changing the color of a chunk of text in response to a rollover is a difficult task in NN4 requiring the careful positioning of a layer atop main page text; and making any inline modification to content (other than swapping an image of the same size) is completely out of the question. Between the IE4+ and W3C DOMs, the biggest differences fall more along operating system and browser brand lines. Microsoft takes advantage of the integration of the IE browser and the Windows operating system to such an extent that it can provide IE services that work only on Windows versions of IE. IE/Mac users are out of luck (for data binding or text filters, for instance), as are NN6 users.

Looking for areas of commonality — or at least gaining a clear understanding of where the models diverge — can be a tedious, yet personally rewarding pursuit. For example, one of the biggest problems facing designers for all three DOMs is the way scripts must reference elements that are to be moved or hidden (something that all three object models can do). NN4 requires references that take the layer object structure into account; IE4+ has the Microsoft syntax of `document.all`, which provides a reference avenue to any element whose ID attribute is set; and the W3C DOM (as implemented in IE5+ and NN6) uses a finger-twisting (albeit now industry standard) `document.getElementById()` method to obtain a reference to any ID'd element.

As soon as your script has a valid reference to an element, the next step is to read or write some property, or invoke some method of that object that governs the element's position (and possibly other style) attributes. Here, again, the object models diverge, but not quite as severely. NN4 has a singular implementation that provides properties and methods of positioned elements (layer objects) directly; the IE4+ and W3C DOMs, on the other hand, work their positioning magic through the `style` property of a positioned element. In some cases the "last-dot" property names are identical across all three models (for example, `document.myLayer.zIndex`, `document.all`).

`myLayer.style.zIndex`, and `document.getElementById("myLayer").style.zIndex`). Building a reference to reach that last dot, though, is where some of your hard work must go.

Each DOM also has its own event model. Whereas IE5+ overlaps its DOM features with both the IE4+ and to some extent the W3C DOM, the event models don't follow the same lines of implementation. As of IE5.5/Windows and IE5/Mac, IE does not implement any of the W3C DOM event model, although NN6 does.

The bottom line, then, is letting your scripts decide how to perform actions based on the browser version is not a good idea. Instead, the scripts should be smart enough to act based on the capabilities of the browser that is currently running the script. As you see in the rest of this chapter, it is possible to develop fairly sophisticated DHTML into a page and make it work with all three DOMs without one iota of browser version detection.

Working Around Incompatibilities

To create DHTML for multiple DOMs, you must find ways to accommodate incompatible object references and occasionally incompatible property names. Scripting gives you several alternatives to working your way around these potential problems. Some of the approaches you can take are now passe, but they are described here partly for the sake of historical reference, but also because you will see many instances of these approaches taken in legacy DHTML applications from the days when authors had to worry about only two DOMS (NN4 and IE4). The real "meat" of this discussion comes later, when you learn more about object detection and custom APIs.

Old-fashioned compatibility tricks

In a simpler time (until late 2000), it was possible to write cross-browser DHTML applications that had to run on only two classes of browser: NN4 and IE4. Two approaches to writing code for these two DOMs grew in popularity: inline branching and platform equivalency. They are described here, not for you to apply, but for you to understand what the pioneers did, in case you encounter their code in your Web surfing.

Inline branching

The idea behind inline branching is that your scripts will use `if...else` decisions to execute one branch of code for one browser and another branch for the other browser. Before you can begin to write code that creates branches for each browser, you should define two global variables at the top of the page that act as Boolean flags for your `if...else` constructions later. Therefore, at the first opportunity for a `<SCRIPT>` tag in a page, include the following code fragment to set flags named `isNav4` and `isIE4`:

```
var isNav4, isIE4
if (parseInt(navigator.appVersion) == 4) {
    if (navigator.appName == "Netscape") {
        isNav4 = true
    } else if (navigator.appVersion.indexOf("MSIE") != -1) {
        isIE4 = true
    }
}
```

Version checking here is quite specific. First of all, it intentionally limits access to browsers whose versions come back as Version 4. This code, written when the browsers were still at Version 4, was remarkably prescient. My concern at the time was that DHTML was so volatile that it was unknown if future browser versions would be backward compatible with the code to be run inside branches governed by the two global variables. As it turned out, NN6 (whose `navigator.appVersion` reports 5) is not backward compatible with the layer structure of NN4, so that locking the NN4 branches to NN4 became a good thing. On the IE side, the `navigator.appVersion` property continues to report 4, even through IE5.5, which is backward compatible with IE4. Thus, any branch dedicated to IE4 executes under this scheme and remains syntactically accurate.

Another aspect of the flag-setting script I should mention is that the example provides no escape route for browsers that aren't level 4 or aren't either Navigator or Internet Explorer (should there be a level 4 browser from another brand). In a production environment, I would either prefilter access to the page or redirect ill-equipped users to a page that explains why they can't view the page. In the structure of the above script, redirection would have to be made in two places, as follows:

```
var isNav4, isIE4
if (parseInt(navigator.appVersion) == 4) {
    if (navigator.appName == "Netscape") {
        isNav4 = true
    } else if (navigator.appVersion.indexOf("MSIE") != -1) {
        isIE4 = true
    } else {
        location = "sorry.html"
    }
} else {
    location = "sorry.html"
}
```

Later in this chapter, I discuss the issue of designing DHTML pages that degrade gracefully in pre-DHTML browsers.

With the global variables defined in the document (and unsupported browsers redirected elsewhere), you can use them as condition values in branching statements that address an object according to the reference appropriate for each platform. For example, to change the `visibility` property of an object named `instructions`, you use the flags as follows:

```
if (isNav4) {
    document.instructions.visibility = "hidden"
} else {
    document.all.instructions.style.visibility = "hidden"
}
```

As the browser DOMs evolve, expand, and fragment, inline branching becomes increasingly less practical. With so many permutations of DOM according to browser brand, browser version, and operating system, you can drive yourself crazy trying to accommodate them all and maintain the code going forward. This approach also eliminates from consideration any non-NN or non-IE browser (such as Opera), which may have the capabilities needed to play your DHTML scripts. This approach also limits the possibility that future browsers with higher `navigator.appVersion` values can take advantage of your scripts.

Platform equivalency

Another technique attempts to limit the concern for the different ways each platform refers to a positionable element (because cross-browser DHTML is pretty much limited to the properties affecting positionable elements). If you examine the formats for each platform's object references, you see that all formats contain a reference to the `document` and to the object name or ID. The IE4+ DOM syntax also includes property words, such as `all` and `style`. If you assign these extra property names to variables for IE4 and leave those variables as empty strings for NN4, you can assemble an object reference for those two platforms in one statement.

To begin using this technique, set two global variables that store reference components for the scope (`all` in IE4) and the `style` object (`style` in IE4):

```
var range = ""
var styleObj = ""
if (parseInt(navigator.appVersion) == 4) {
    if (navigator.appVersion.indexOf("MSIE") != -1) {
        range = "all."
        styleObj = ".style"
    }
}
```

From this point, you can assemble an object reference with the help of the JavaScript `eval()` function, as follows:

```
var instrux = eval("document." + range + "instructions" + styleObj)
instrux.visibility = "hidden"
```

Or, you can use the `eval()` function to handle the entire property assignment in one statement, as follows:

```
eval("document." + range + "instructions" + styleObj + ".visibility = 'hidden'")
```

If your page does not have a lot of objects that your scripts will be adjusting, you can use this platform equivalency approach to create global variables holding references to your positionable objects at load time (triggered by the `onLoad` event handler so that all objects exist and can be referenced by the `eval()` function). Then, use those variables for object references throughout the scripts.

Unfortunately, the platform equivalency methodology breaks down when a NN4 layer object is nested inside another layer. The platform equivalency formulas assume that each object is directly addressable from the outermost `document` object. If your objects have a variety of nested locations, you can use either the inline branching method described earlier, or batch-assign objects to global variables at load time using platform branching techniques along the lines of the following example:

```
var instrux
function initObjectVars() {
    if (isNav4) {
        instrux = document.outerLayer.document.instructions
    } else {
        instrux = document.all.instructions.style
    }
}
```

As soon as the variable contains a valid reference to the object for the current platform, your scripts can treat the object without further concern for platform when addressing properties that have the same name in both platforms:

```
instrux.visibility = "hidden"
```

The nested layer situation is not the only potential problem for the platform equivalency approach. In fact, the W3C DOM format for referencing objects (using the `document.getElementById()` method) makes for some hair-raising string assembly and global variable assignment. Another truly negative aspect is the frequent usage of the `eval()` function. As mentioned in Chapter 42, this function is a performance speed thief.

Modern approaches to compatibility

While in-line branching and platform equivalency were suitable for their generations, the profusion of browser versions calls for better approaches to simplifying authoring for multiple DOMs. Techniques more suitable for today—object detection and custom APIs—are not really new. But these techniques are the preferred way to build cross-browser scripts with an eye to compatibility both backward and forward.

Object detection

The subject of object detection has been mentioned in several places in earlier chapters of this book. The technique has been used for a long time to let a browser not equipped to handle image objects gracefully skip over image swapping script segments:

```
if (document.images) {  
    // statements to work with image objects  
}
```

If there is no `document.images` property for a browser, the condition evaluates to `undefined`, which the condition treats as being `false`.

But object detection has also been misused in the past, especially in the DHTML realm, to substitute for browser version detection. For example, if a browser supported the `document.all` collection, a global variable was set to indicate that the browser was IE4 or later; the existence of `document.layers` supposedly meant that the browser was NN4. While both of those assertions are true (as of the browsers released so far), it was a mistake to link a browser version with the existence of an object or property. Instead, object detection should be used only if your script statements will be addressing that object, just as the `document.images` condition does in the previous example.

To demonstrate this tactic, consider the need to assemble a reference to an object so that it is ready to have one of its DHTML properties adjusted. Each of the three DOMs has its own syntax for assembling such a reference, and each syntax relies on the existence of a particular object or property. The function shown in Listing 47-1 (not on the CD-ROM by itself, but included in Listing 47-2) lets you pass the name or ID of a positioned element (either in string form or object form) to receive back a valid reference to the object with which style-related properties are associated—all without resorting to the `eval()` function in any form:

Listing 47-1: Using Object Detection to Assemble an Element Object Reference

```
function getObject(obj) {
    var theObj
    if (document.layers) {
        if (typeof obj == "string") {
            // just one layer deep
            return document.layers[obj]
        } else {
            // can be a nested layer
            return obj
        }
    }
    if (document.all) {
        if (typeof obj == "string") {
            return document.all(obj).style
        } else {
            return obj.style
        }
    }
    if (document.getElementById) {
        if (typeof obj == "string") {
            return document.getElementById(obj).style
        } else {
            return obj.style
        }
    }
    return null
}
```

The primary object detection for each of the three sections of this function looks for the presence of categories of objects (`document.layers` and `document.all`) or a particular method (`document.getElementById()`), and then—this is the important part—the script uses those detected objects in the statements. The script doesn't know IE4 from NN6; it *does* know how to derive valid references for three different object models, and employs the syntax of the first one for which the associated object property or method is supported.

In practice, the order of the three sections should have no bearing on your scripts, but you should be aware of one subtlety: IE5+ can work with either of the last two sections, because those browsers detect `document.all` and `document.getElementById` as valid references. If you were to switch the position of the last two sections, then IE5+ would be using W3C DOM terminology. The results, however, are the same: A valid reference to the `style` object associated with an element.

Custom APIs

Notions of object detection and simplifications of your scripts come together in the final approach to building cross-browser DHTML: Writing a custom API (Application Programming Interface). A JavaScript custom API is a library of

functions you design to act as an intermediary between your scripts and other scriptable entities. Ideally, an API simplifies access to, or control of, other entities. In the context of designing a cross-browser DHTML page, an API can offer a single function that smoothes over the differences in object references and/or property names among several platforms. Your custom function provides a single access point that is consistent across all platforms. In essence, you are creating your own metavocabulary for methods and property settings.

The element object reference maker in Listing 47-1 is a good start for such an API, because all other functions for moving, hiding, showing, and changing the stacking order of a positionable element need a valid style-oriented reference to the element. Now look at a function from an API whose job is to alter the stacking order of a positionable element:

```
// set the z-order of an object
function setZIndex(obj, zOrder) {
    var theObj = getObject(obj)
    theObj.zIndex = zOrder
}
```

Your main page script would use the ID of the positioned DIV element as the first parameter to this function, with an integer indicating the value that would be assigned to the element's style sheet `z-Index` attribute:

```
setZIndex("myLayer", 100)
```

All of the branching for the various DOMs in this function is done in the `getObject()` function (Listing 47-1), which returns the valid reference for whichever of the three supported DOMs is running the script. All three DOMs, it turns out, have the same `zIndex` property representing the `z-Index` style attribute, so that no further branching is needed here.

As one more example, the next API function offers an interface to incompatible ways of adjusting the location of a positionable element. In this case, the act of moving an element has different syntax in different DOMs. One group (NN4 for layers) uses the `moveTo()` method; the rest support `left` and `top` properties of their `style` object:

```
// position an object at a specific pixel coordinate
function shiftTo(obj, x, y) {
    var theObj = getObject(obj)
    if (theObj.moveTo) {
        theObj.moveTo(x,y)
    } else if (typeof theObj.left != "undefined") {
        theObj.left = x
        theObj.top = y
    }
}
```

Notice one workaround, which, on the surface, isn't pretty: The second branch must perform an odd way of object detection. We're stuck with having to make a tradeoff when it comes to checking for the existence of a style property. If the page uses style sheets defined in `<STYLE>` tags (or imported into the page from external style sheet files), the element affected by the rule does not yield the rule's property values through the element's `style` property. The property exists, but its value in

this case (or until it is set by script) is an empty string. IE5 provides a `currentStyle` property to give us the effective values, but that property is not (yet) a part of the DOM standard. But even if you assign the style sheet via the element's `STYLE` attribute (in which case the style property values come through), detecting the presence of the property with the conditional expression

```
if (theObj.left)
```

is not practical here anyway. If the effective value of the `left` and `top` properties were an empty string (or zero for a numeric style property value), the conditional expression would evaluate to the equivalent of `false`, making it appear as though the property doesn't exist. To validate the existence of the property, the conditional expression verifies that the value of a named property has a type other than "undefined." It may seem like a long way to go to prove the existence of a property, but it works, even if the value is an empty string or zero.

It is important that both branches perform object detection. Although it is unlikely (but, as we learned from the transition between NN4 and NN6, not impossible), if a future browser should completely alter its vocabulary, omitting the objects being detected here, the function ends gracefully, without generating script errors.

An API is usually best deployed as an external `.js` file. One such API file is described later in this chapter. Bear in mind, however, that a lengthy API gets downloaded to the browser, no matter how much or how little of it your main scripts use. Blindly linking in a big library just to use a few of its functions is a mistake. You serve your users better if you create a subset of the API, and link the subset to the page (or drop the few functions directly into the page's scripts if the combination is not reused on a lot of pages).

Handling non-DHTML browsers

An important question to ask yourself as you embark on a DHTML-enhanced page is how you intend to treat visitors whose browsers aren't up to the task. In many respects the problem is similar to the problem of treating nonscriptable browsers when your page relies on scripting (see Chapter 13).

The moment your page uses DHTML to position an element, you must remember that non-DHTML browsers display the content according to traditional HTML rendering rules. No elements are allowed to overlap. Any block-level tag is rendered at the left margin of the page, unless some other non-DHTML alignment (center or right) is at work. This goes for elements that you design to be DHTML-positioned to sit offscreen (perhaps with a clickable tab) until called by the user. An element defined as being hidden or not displayed in DHTML will be visible. In most cases, your carefully designed DHTML page will look terrible.

However, a page that does not use too radical a layout strategy may still be usable in non-DHTML browsers. You should always check your DHTML-enabled page in an older browser to see how it looks. Perhaps there isn't too much you need to do to degrade the DHTML so that the page is acceptable in older browsers.

The ultimate responsibility for deciding your compatibility strategy with older browsers rests with you and your perceptions about your page visitors. If they are in need of vital information from your site and that information is readable in non-DHTML browsers, then that may be enough. Otherwise, you must provide a

separate content path for both levels of browsers, much as you may be doing for scriptable versus nonscriptable browsers.

A DHTML API Example

Now it's time to get to a real DHTML API that you can use and build upon for your own applications. Listing 47-2 contains the API code, which is most likely to be deployed as an external `.js` library file. In fact, this API is used as-is in a map puzzle game application in Chapter 56. You can see there how it is used to control element positioning, dragging, and layering for the three DOM families. The code in Listing 47-2 is longer than most listings in this book, so for your convenience, I interlace commentary amid the long listing.

No global variables are needed for this API. Because all browser branching is performed via object detection, there is no need for browser version detection. Instead, the library starts with the `getObject()` function shown earlier in this chapter. Virtually every other function in this library makes a trip to `getObject()` to convert the name of the object passed as a parameter to an object reference whose positionable (or other style-related property) can be adjusted.

Listing 47-2: The Custom API (DHTMLapi.js)

```
// convert object name string or object reference
// into a valid object reference ready for style change
function getObject(obj) {
    var theObj
    if (document.layers) {
        if (typeof obj == "string") {
            return document.layers[obj]
        } else {
            return obj
        }
    }
    if (document.all) {
        if (typeof obj == "string") {
            return document.all(obj).style
        } else {
            return obj.style
        }
    }
    if (document.getElementById) {
        if (typeof obj == "string") {
            return document.getElementById(obj).style
        } else {
            return obj.style
        }
    }
    return null
}
```

A pair of functions handles all motion of positionable elements. The first function, `shiftTo()` takes three parameters: the ID of the object being moved, and the horizontal and vertical pixel coordinates of the top-left corner of the element. The assumption is that the main page script that invokes this library function performs the calculation of the coordinates. You see that code in Chapter 56. Branches inside this function handle the NN4 `layer.moveTo()` method or the setting of `style` properties for other DOMs. In these other browsers, moving the element requires adjusting two positional properties, `left` and `top`. Even though the adjustments are made in separate statements, the action on the screen does not follow the action statement-by-statement. Between screen buffering and quick execution, the repositioning appears as a single shift.

```
// position an object at a specific pixel coordinate
function shiftTo(obj, x, y) {
    var theObj = getObject(obj)
    if (theObj.moveTo) {
        theObj.moveTo(x,y)
    } else if (typeof theObj.left != "undefined") {
        theObj.left = x
        theObj.top = y
    }
}
```

The `shiftBy()` function mimics NN4's `layer.moveBy()` method. The second and third parameters represent the number of pixels that the object should be moved on the page. A positive number means to the right or down; a negative number means to the left or up; a value of zero means no change to the axis. For NN4, the script uses the `layer.moveBy()` method. But for the rest, the passed values are added to the `left` and `top` properties. Notice that because these properties return strings that include the units for the measurements, the incremental values are added to integer extractions from the current settings. And because the units being used here are the default (pixels), no units have to be assigned with the new values (although they could without penalty).

```
// move an object by x and/or y pixels
function shiftBy(obj, deltaX, deltaY) {
    var theObj = getObject(obj)
    if (theObj.moveBy) {
        theObj.moveBy(deltaX, deltaY)
    } else if (typeof theObj.left != "undefined") {
        theObj.left = parseInt(theObj.left) + deltaX
        theObj.top = parseInt(theObj.top) + deltaY
    }
}
```

Both platforms use the same property name for setting the stacking order of positionable things. Therefore, the `setZIndex()` function does little more than convert the object reference and assign the incoming value to the `zIndex` property.

```
// set the z-order of an object
function setZIndex(obj, zOrder) {
    var theObj = getObject(obj)
    theObj.zIndex = zOrder
}
```

NN4 and browsers with style objects have their own way of referring to the background color. The `setBGColor()` function applies the correct syntax based on whichever property is detected in the object.

```
// set the background color of an object
function setBGColor(obj, color) {
    var theObj = getObject(obj)
    if (theObj.bgColor) {
        theObj.bgColor = color
    } else if (typeof theObj.backgroundColor != "undefined") {
        theObj.backgroundColor = color
    }
}
```

Allowable values for the `visibility` property are very unprogrammatic in my opinion. I expect a Boolean value rather than strings. To accede to reality while making the process of showing and hiding elements more logical to me, I created API functions called `show()` and `hide()`.

```
// set the visibility of an object to visible
function show(obj) {
    var theObj = getObject(obj)
    theObj.visibility = "visible"
}

// set the visibility of an object to hidden
function hide(obj) {
    var theObj = getObject(obj)
    theObj.visibility = "hidden"
}
```

Although the `left` and `top` properties of NN4 layers do not include unit values, it is still safe to use `parseInt()` on the values returned from the properties, whether they be retrieved in NN4 or browsers that have style objects (whose properties return units). The need for these API functions came from the way the map puzzle application in Chapter 56 works. For a couple of operations, it calculates the destination for an object with respect to the position of one of the other positioned elements. These functions return the values needed for the main program's calculation. This is also an example of how you may need to embellish the API for your own application.

```
// retrieve the x coordinate of a positionable object
function getObjectLeft(obj) {
    var theObj = getObject(obj)
    return parseInt(theObj.left)
}

// retrieve the y coordinate of a positionable object
function getObjectTop(obj) {
    var theObj = getObject(obj)
    return parseInt(theObj.top)
}
```

The previous API is generalizable enough to be used as a library with any cross-platform DHTML application using positioning. The API can even be used with a platform-specific page. It is more efficient, however, to use a browser's native objects, properties, and methods if you know for sure that users will have only one brand of browser.

Internet Explorer Behaviors

Internet Explorer 5 for Windows was the first browser to deploy what Microsoft calls *behaviors*. Microsoft and others have proposed the behaviors concept to the W3C, and it could some day become one of the W3C standard recommendations. Such a standard might not be implemented exactly the way Microsoft currently implements behaviors, but most of the concepts are the same, and the syntax being discussed so far is similar. While there is no guarantee that the W3C will adopt behaviors as a standard, you will see that the concept seems to be a natural extension to the work that has already been adopted for both CSS and XML. Even though behaviors run only on Windows versions of IE5+ (as of this writing anyway), that browser family and operating system are pervasive enough to warrant an extended description of how behaviors work.

The W3C effort is called Behavioral Extensions to CSS. For the latest document describing the work of the participants of the standards discussions, visit <http://www.w3.org/TR/becss>.

Style Sheets for Scripts

You can best visualize what a behavior is in terms of the way you use style sheets. Consider a style sheet rule whose selector is a tag or a class name. The idea behind the style sheet is that one rule, which can define dozens of rendering characteristics of a chunk of HTML content, can be applied to perhaps dozens, if not hundreds, of elements within the document. A corporation may design a series of rules for the way its Web documents will look throughout the Web site. If the designer decides to alter the font family or color for, say, H1

48

CHAPTER

In This Chapter

Introducing IE behaviors

Understanding the structure of behavior XML files

Exploring behavior samples

elements, then that change is made in one place (the external style sheet file), and the impact is felt immediately across the entire site. Any page that includes an H1 element renders the header with the newly modified style.

Imagine now that instead of visual styles associated with an element, you want to define a *behavioral style* for a particular group of elements. A behavioral style is the way an element responds to predominantly user interaction with the element. For example, if the design specifications for a Web site indicate that all links should have their text colored a certain way when at rest, but on mouse rollovers, the text color changes to a more contrasting color, the font weight increases to bold, and the text becomes underlined. Those modifications require scripts to change the style properties of the element in response to the mouse action of the user. The scripts that fire in response to specific user actions (events) are written in an external file known as a behavior, and a behavior is associated with an element, class, or tag through the same CSS syntax that you use for other style attributes.

A behavior, of course, assumes that its scripts can work with whatever HTML element is associated with the behavior. Just as it would be illogical to associate the `tableLayout` style attribute with an element that wasn't a TABLE, so, too, would it be illogical to associate a behavior, whose scripts employed TABLE object properties and methods, to a P element. Even so, a well-designed behavior can obtain details about the element being manipulated through the element object's properties. The better you are at writing generalizable JavaScript functions, the more successful you will be in implementing behaviors.

Embedding Behavior Components

IE treats each behavior as a component, or add-on building block for the browser. IE5 comes equipped with a handful of behaviors built into the browser (the so-called default behaviors, which happen to rely on specific XML elements embedded in a document). Behaviors that you create most likely exist as separate files on the server, just like external `.css` and `.js` files do. The file extension for a behavior file is `.htc` (standing for HTML Component).

Linking in a behavior component

To associate a behavior with any single element, class of elements, or tag as the page loads, use CSS rule syntax and the IE-specific `behavior` attribute. The basic syntax is as follows:

```
selector {behavior:url(componentReference)}
```

As with any style sheet rule, you can combine multiple rule attributes, delimiting them with semicolons. The format of the *componentReference* depends on whether you are using one of the IE default behaviors or a behavior you've written to an external file. For default behaviors, the reference is in the format:

```
#default#componentName
```

For example, if you want to associate the `download` behavior with any element of class `downloads`:

```
.downloads {behavior:url(#default#download)}
```

Relative or absolute URIs to external `.htc` files can also be specified. For example, if your site contains a directory named `behaviors` and a file named `hilite.htc`, the style sheet rule from the root directory is:

```
.hilite {behavior:url(behaviors/hilite.htc)}
```

As with all CSS style sheet rules, behaviors can be specified in a `STYLE` element of the page, in the `STYLE` attribute of an individual element, or in a rule defined inside an imported `.css` file.

Enabling and disabling behaviors

In Chapter 15, you can find details of IE5/Windows methods for all HTML elements that let scripts manage the association of a behavior with an element after the page has loaded. Invoking the `addBehavior()` method on an element assigns an external `.htc` file to that element. When you no longer need that behavior associated with the element, invoke the `removeBehavior()` method.

Component Structure

An `.htc` behavior file is a text file consisting of script statements inside a `<SCRIPT>` tag set and some special XML tags that IE5/Windows knows how to parse. You create `.htc` files in the same kind of plain text editor that you use for external `.js` or `.css` files.

Script statements

Unlike external `.js` files, an `.htc` behavior file includes `<SCRIPT>` tags, which surround any JavaScript (or VBScript, if you like) statements that control the behavior. Because a behavior most typically is written to control one or more aspects of the HTML element to which it is connected, statements tend to operate only on the associated object element. A special reference—`element`—is used to refer to the element object itself (much like the way the `this` keyword in a custom object's method self-refers to the object associated with the method).

If your behavior will be modifying either the content or style of the element, use the `element` reference as a foundation to the reference to one of that element object's properties or methods. For example, if a statement in a behavior needs to set the `style.visibility` property so that the element hides itself, the statement in the behavior script is:

```
element.style.visibility = "hidden"
```

Any valid reference from the point of view of the element object is fair game, including references to the element's `parentElement`, even though the parent element is not explicitly associated with the behavior.

Variable scope

Except for the special `element` reference, script content of a behavior is completely self-contained. You can define global variables in the behavior that are accessible to any script statement in the behavior. But a global variable in a behavior does not become a global variable for the main document's scripts to

use. You can expose variables so that scripts outside of the behavior can get to them (as described below), but this exposure is not automatic.

Most of the script content of a behavior consists of functions that usually interact in some fashion with the associated element (via the element's properties and/or methods). Local variables in functions have the same scope and operate just like they do in regular script functions. Global variables you define in a behavior, if any, are usually there for the purpose of preserving values between separate invocations of the functions.

Assigning event handlers

Functions in a behavior are triggered from outside the behavior through two means: event handlers and direct invocation of functions declared as public (described in the next section). Event handler binding is performed in a way that is not used elsewhere in the IE4+ DOM. Each event type (for example, `onMouseOver`, `onKeyPress`) requires its own special XML tag at the top of the behavior file. The format for the event handler tag is as follows:

```
<PUBLIC:ATTACH EVENT="eventName" ONEVENT="behaviorFunctionName()" />
```

As the behavior loads, the `PUBLIC:ATTACH` tag instructs the browser to expose to the “public” (that is, the world outside of the behavior) an event type (whose name always begins with the “on” prefix in the IE4+ event model); whenever an event of that type reaches the behavior's element, then the function (defined within the behavior file) is invoked. In XML terminology, the `PUBLIC:` part of the tag is known as a *namespace*, and IE includes a built-in parser for the `PUBLIC` namespace. Notice, too, the XML syntax at the end of the tag that allows a single set of angle brackets to act as a start and end tag set (there is no content for this tag, just the attributes and their values).

To demonstrate, imagine that a behavior has a function named `underlineIt()`, which sets the `element.style.textDecoration` property to `underline`. To get the element to display the underline decoration as the user rolls the mouse atop the element, bind this function to the element's `onMouseOver` event handler as follows:

```
<PUBLIC:ATTACH EVENT="onmouseover" ONEVENT="underlineIt()" />
```

If you compare the wording of the opening part of the tag, you may recognize a connection to the IE4+ event model's `attachEvent()` method of all HTML elements (Chapter 15). You can have as many event binding tags as your element needs. To invoke multiple functions in response to a single event type, simply add the subsequent function invocation statements to the `ONEVENT` attribute, separating the calls by semicolons (the same as with regular JavaScript statement delimiters).

Exposing properties and methods

XML tags with the `PUBLIC:` namespace are also used (with different attributes) to expose a behavior's global variables as properties of the element and a behavior's functions as methods of the element. The syntax for both types of “public” announcements is as follows:

```
<PUBLIC:PROPERTY NAME="globalVarName" />
<PUBLIC:METHOD NAME="functionName" />
```

Values for both items are string versions of references to the variable and function (no parentheses). Again, you can define as many properties and methods for a behavior as you need.

As soon as a property and/or method is made public in a behavior, scripts from outside the behavior can access those items as if they were properties or methods of the element associated with the behavior:

```
document.all.elementID.behaviorProperty  
document.all.elementID.behaviorMethod()
```

If you associate a behavior with a style sheet class selector, and several document elements share that class name, each one of those elements gains the public properties and methods of that behavior, accessible through references to the individual elements. That's because a behavior's scripts are written to read or modify properties of whatever element receives a bound event or is referenced along the way to the public property or method.

Behavior Examples

The two following examples are intentionally simple to help you grasp the concepts of behaviors if they are new to you. The first example interacts with multiple elements strictly through event binding; the second example exposes a property and method that the main page's scripts access to good effect.

Example 1: Element dragging behavior

This book contains several examples of how to script a page to let a user drag an element around the browser window (Chapters 31 and 56 in particular). In all those examples, the dragging code and event handling was embedded in some fashion into the page's scripts. The first example of a behavior, however, drives home the notion of separating an element's behavior from its content (just as a CSS2 style sheet separates an element's appearance from its content).

Imagine that it's your job to design a page that employs three draggable elements. Two of the elements are images, while the third is a panel layer that also includes a form. If you haven't scripted DHTML before, this may sound like a daunting task at first, one rife with the possibility of including multiple versions of the same scripts to accommodate different kinds of draggable elements.

Now imagine that to the rescue comes a scripter who has built a behavior that takes care of all of the dragging scripting for you. All you do is assign that behavior by way of one attribute of each draggable element's style sheet rule. Absolutely no other scripting is required on the main page to achieve the element dragging.

Listing 48-1 shows the behavior file (`drag.htc`) that controls basic dragging of a positionable element on the page. You may recognize some of the code as an IE4+ version of the cross-browser dragging code used elsewhere in this book (for a blow-by-blow account of these functions, see the description of the map puzzle game in Chapter 56). The names of the three operative functions and the basic way they do their jobs are identical to the other dragging scripts. Event binding, however, follows the behavior format through the XML tags. All interaction with the outside world occurs through the "public" event handlers.

Listing 48-1: An Element Dragging Behavior

```
<PUBLIC:ATTACH EVENT="onmousedown" ONEVENT="engage()" />
<PUBLIC:ATTACH EVENT="onmousemove" ONEVENT="dragIt()" />
<PUBLIC:ATTACH EVENT="onmouseup" ONEVENT="release()" />
<PUBLIC:ATTACH EVENT="onmouseover" ONEVENT="setCursor()" />
<PUBLIC:ATTACH EVENT="onmouseout" ONEVENT="release();restoreCursor()" />

<SCRIPT LANGUAGE="JScript">
// global declarations
var offsetX = 0
var offsetY = 0
var selectedObj
var oldZ, oldCursor

// initialize drag action on mousedown
function engage() {
    selectedObj = (element == event.srcElement) ? element : null
    if (selectedObj) {
        offsetX = event.offsetX - element.document.body.scrollLeft
        offsetY = event.offsetY - element.document.body.scrollTop
        oldZ = element.runtimeStyle.zIndex
        element.style.zIndex = 10000
        event.returnValue = false
    }
}

// move element on mousemove
function dragIt() {
    if (selectedObj) {
        selectedObj.style.pixelLeft = event.clientX - offsetX
        selectedObj.style.pixelTop = event.clientY - offsetY
        event.cancelBubble = true
        event.returnValue = false
    }
}

// restore state on mouseup
function release() {
    if (selectedObj) {
        selectedObj.style.zIndex = oldZ
    }
    selectedObj = null
}

// make cursor look draggable on mouseover
function setCursor() {
    oldCursor = element.runtimeStyle.cursor
    element.style.cursor = "hand"
}
```

```
// restore cursor on mouseout
function restoreCursor() {
    element.style.cursor = oldCursor
}
</SCRIPT>
```

Notice a subtlety in Listing 48-1 that is implied by the element-specific scope of a behavior. Two statements in the `engage()` function need to reference scroll-related properties of the `document.body` object. Because the only connection between the behavior and the document is via the `element` reference, that reference is used along with the `document` property (a property of every HTML element object in IE4+, as shown in Chapter 15). From there, the `body` object and the required properties can be accessed.

Listing 48-2 is a simple page that contains three elements that are associated with the `drag.htc` behavior through a style sheet rule definition (for the `draggable` class). The document is incredibly uncomplicated. Even the `drag.htc` file isn't very big. But together they produce a far more interesting page for the user than a couple of static images and a form.

Listing 48-2: Three Draggable Elements Using the Behavior

```
<HTML>
<HEAD>
<STYLE TYPE="text/css">
.draggable {position:absolute; behavior:url(drag.htc)}
#img1 {left:150px; top:150px}
#img2 {left:170px; top:170px}
#txt1 {left:190px; top:190px; background-color:aqua; width:150px; height:50px;
text-align:center}
</STYLE>
</HEAD>

<BODY>
<H1>IE5+ Behavior Demo (Dragging)</H1>
<HR>
<IMG CLASS="draggable" ID="img1" SRC="cpu1.gif">
<IMG CLASS="draggable" ID="img2" SRC="desk3.gif">
<DIV CLASS="draggable" ID="txt1">A form inside a DIV element.
  <FORM>
    <INPUT TYPE="button" VALUE="Does Nothing">
  </FORM>
</DIV>
</BODY>
</HTML>
```

Obviously, the dragging example here is very rudimentary. It isn't clear from the sample code what the user gets from the page, other than the joy of moving things around. If you were designing an application that genuinely benefits from draggable

objects (for example, the map puzzle in Chapter 56), you can easily enhance the behavior to perform actions, such as snapping a dragged element into place when it is within a few pixels of its proper destination. For such an implementation, the behavior can be given some extra global variables, akin to the values assigned to the state objects in Chapter 56, including the pixel coordinates of the ideal destination for a dragged element. An `onLoad` event handler for the page can fire a public `init()` function in each element's behavior to assign those coordinate values. Any event that can bubble (such as mouse events) does so from the behavior to the target. Therefore, you can extend the event action of the behavior by adding a handler for the same event to the element outside of the behavior.

Example 2: Text rollover behavior

In the second example, you see how a behavior exposes a global variable and function as a public property and method, respectively. The demonstration reinforces the notion that even if a single behavior file is associated with multiple elements (for example, the elements share the same class, and the behavior is assigned to the class), each behavior maintains its own variable values, independent of the other elements and their behaviors.

The nature of this behavior is to set the `color` style property of the associated element to either a default color (red) or to another color that has been passed into the behavior via one of its public methods. The color setting is preserved in one of the behavior's global variables, and that variable is exposed as a public property.

Listing 48-3 shows the `.htc` behavior file's content. Only two events are bound to this behavior: `onmouseover` and `onmouseout` — the typical rollover events. The `onmouseover` event invokes the `makeHot()` function, while the `onmouseout` event invokes the `makeNormal()` function. Before the `makeHot()` function makes any changes to the `color` and `fontWeight` style properties of the element, existing settings are preserved in (non-public) global variables in the behavior. This allows the `makeNormal()` function to restore the original settings, regardless of what document styles may be applied to the element in a variety of pages. That's something to keep in mind when you design behaviors: they can be deployed in pages controlled by any number of style sheets. Don't assume any basic style setting; instead, use the `currentStyle` property to read and preserve the effective property values before touching them with your behavior's modification scripts.

Neither of the event handler functions are exposed as public methods. This was a conscious decision for a couple of reasons. The most important reason is that both functions rely on being triggered by a known event occurring on the element. If either function were invoked externally, the event object would contain none of the desired information. Another reason behind this is from a common programming style for components that protects inner workings, while exposing only those methods and properties that are "safe" for others to invoke. For this code, the public method does little more than set a property. It's an important property, to be sure, and one of the protected functions relies on it. But by allowing the public method little room to do any damage other than execution of the behavior, the design makes the behavior component that more robust.

Assigning a color value to the public property and passing one as a parameter to the public method accomplishes the same result in this code. As you will see, the property gets used in the demonstration page to retrieve the current value of the global variable. In a production behavior component, the programmer would probably choose to expose this value strictly as a read/write property or expose two

methods, one for getting and one for setting the value. The choice would be at the whim of the programmer's style and would likely not be both. Using a method, however, especially for setting a value, creates a framework in which the programmer can also perform validation of the incoming value before assigning it to the global variable (something the example here does not do).

Listing 48-3: Rollover Behavior (makeHot.htc)

```
<PUBLIC:ATTACH EVENT="onmouseover" ONEVENT="makeHot()" />
<PUBLIC:ATTACH EVENT="onmouseout" ONEVENT="makeNormal()" />
<PUBLIC:PROPERTY NAME="hotColor" />
<PUBLIC:METHOD NAME="setHotColor" />
<SCRIPT LANGUAGE="JScript">
var oldColor, oldWeight
var hotColor = "red"

function setHotColor(color) {
    hotColor = color
}

function makeHot() {
    if (event.srcElement == element) {
        oldColor = element.currentStyle.color
        oldWeight = element.currentStyle.fontWeight
        element.style.color = hotColor
        element.style.fontWeight = "bold"
    }
}

function makeNormal() {
    if (event.srcElement == element) {
        element.style.color = oldColor
        element.style.fontWeight = oldWeight
    }
}
</SCRIPT>
```

To put the public information and the behavior, itself, to work, a demonstration page includes three spans within a paragraph that are associated with the behavior. Listing 48-4 shows the code for the demo page.

In addition to the text with rollover spans, the page contains two SELECT controls, which let you assign a separate color to each of the three elements associated with the behavior. The first SELECT element lets you choose one of the three elements. Making that choice invokes the `readColor()` function in the same page. This is the function that reads the `hotColor` public property of the chosen span. That color value is used to select the color name for display in the second SELECT element. If you make a choice in the list of colors, the `applyVals()` function invokes the public `setHotColor()` method of the element currently selected from the list of elements. Rolling the mouse over that element now highlights in the newly selected color, while the other elements maintain their current settings.

Listing 48-4: Applying the Rollover Behavior

```

<HTML>
<HEAD>
<STYLE TYPE="text/css">
.hotStuff {font-weight:bold; behavior:url(makeHot.htc)}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function readColor(choice) {
    var currColor = document.all(choice.value).hotColor
    var colorList = choice.form.color
    for (var i = 0; i < colorList.options.length; i++) {
        if (colorList.options[i].value == currColor) {
            colorList.selectedIndex = i
            break
        }
    }
}
function applyVals(form) {
    var elem = form.elem.value
    document.all(elem).setHotColor(form.color.value)
}
</SCRIPT>
</HEAD>

consequat</SPAN>.</P>
</DIV>
</BODY>
</HTML>

```

Behaviors are not the solution for every scripting requirement. As demonstrated here, they work very well for generic style manipulation, but you are certainly not limited to that sphere. By having a reference back to the element associated with the behavior, and then to the document that contains the element, a behavior's scripts can have free run over the page—provided the actions are either generic among any page or generic among a design template that is used to build an entire Web site or application.

Even if you don't elect to use behaviors now (perhaps because you must support browsers other than IE/Windows), they may be in your future. Behaviors are fun to think about and also instill good programming practice in the art of creating reusable, generalizable code.

For More Information

In addition to the address of W3C activity on behaviors, Microsoft devotes many pages of its developer site to behaviors. Here are some useful pointers.

Overview:

<http://msdn.microsoft.com/workshop/author/behaviors/overview.asp>

Using DHTML Behaviors:

CHAPTER

Application: Tables and Calendars

Working with HTML tables is a lot of fun, especially if, like me, you are not a born graphics designer. By adding a few tags to your page, you can make your data look more organized, professional, and appealing. Having this power under scripting control is even more exciting, because it means that in response to a user action or other variable information (such as the current date or time), a script can do things to the table as the table is being built. In IE4+ and W3C DOMs, scripts can modify the content and structure of a table even after the page has loaded, allowing the page to almost “dance.”

You have three options when designing scripted tables for your pages, although only two are backward compatible with non-DHTML browsers:

- ◆ Static tables
- ◆ Dynamic tables
- ◆ Dynamic HTML tables

The design path you choose is determined by whether you need to dynamically update some or all fields of a table (data inside `<TD> . . . </TD>` tags) and which browser levels you need to support. To highlight the differences among the three styles, this chapter traces the implementation of a monthly calendar display in all three formats.

About the Calendars

Because the emphasis here is on the way tables are scripted and displayed, I quickly pass over structural issues of the calendar versions described in the following sections. The first two examples are backward compatible to the earliest browsers that didn't even know genuine Array objects.

In This Chapter

Accommodating older browsers

Scripted tables

Date calculations

The final example, however, is a much more modern affair, utilizing table-related DOM objects and methods to simplify the code. It requires IE4+ for Windows (unfortunately, a bug in IE/Mac causes problems with the amount of TABLE object modification the script does) and NN6.

All three calendars follow similar (if not over-simplified) rules for displaying calendar data. English names of the months are coded into the script, so that they can be plugged into the calendar heading as needed. To make some of the other calendar calculations work (such as figuring out which day of the week is the first day of a given month in a given year), I define a method for my month objects. The method returns the JavaScript date object value for the day of the week of a month's first date. Virtually everything I do to implement the month objects is adapted from the custom objects discussion of Chapter 34.

Static Tables

The issue of updating the contents of a table's fields is tied to the nature of an HTML document being loaded and fixed in the browser's memory. Recall that for early browsers, you can modify precious few elements of a document and its objects after the document has loaded. That case certainly applies for typical data points inside a table's <TD> tag pair. After a document loads—even if JavaScript has written part of the page—none of its content (except for text and textarea field contents and a few limited form element properties) can be modified without a complete reload.

Listing 49-1 contains the static version of a monthly calendar. The scripted table assembly begins in the Body portion of the document. Figure 49-1 shows the results.

Listing 49-1: A Static Table Generated by JavaScript

```
<HTML>
<HEAD>
<TITLE>JavaScripted Static Table</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// function becomes a method for each month object
function getFirstDay(theYear, theMonth){
    var firstDate = new Date(theYear,theMonth,1)
    return firstDate.getDay() + 1
}
// number of days in the month
function getMonthLen(theYear, theMonth) {
    var oneDay = 1000 * 60 * 60 * 24
    var thisMonth = new Date(theYear, theMonth, 1)
    var nextMonth = new Date(theYear, theMonth + 1, 1)
    var len = Math.ceil((nextMonth.getTime() -

Figure 49-1: The static table calendar generated by Listing 49-1

In this page, a little bit of the HTML—the `<H1>` heading and `<HR>` divider—is unscripted. The rest of the page consists entirely of the table definition, all of which is constructed in JavaScript. Though you may want to interlace straight HTML and scripted HTML within the table definition, bugs exist in NN2 and NN3 that make this tactic hazardous. The safest method is to define the entire table from the `<TABLE>` to `</TABLE>` tags in JavaScript and post it to the page in one or more `document.write()` methods.

Most of the work for assembling the calendar's data points occurs inside of the `for` loop. Because not every month starts on a Sunday, the script determines the day of the week on which the current month starts. For all fields prior to that day, the `for` loop writes empty `<TD></TD>` tags as placeholders. After the numbered days of the month begin, the `for` loop writes the date number inside the `<TD> . . . </TD>` tags. Whatever the script puts inside the tag pair is written to the page as flat HTML. Under script control like that in the example, however, the script can designate what goes into each data point—rather than writing fixed HTML for each month's calendar.

The important point to note in this example is that although the content of the page may change automatically over time (without having to redo any HTML for the next month), after the page is written, its contents cannot be changed. If you want to add controls or links that are to display another month or year, you have to rewrite the entire page. This can be accomplished by passing the desired month and year as a search string for the current page's URL and then assigning the combination to the `location.href` property. You also have to add script statements to the page that look for a URL search string, extract the passed values, and use those values to generate the calendar while the page loads (see Chapter 17 for examples of how to accomplish this feat). But to bring a calendar such as this even more to life (while avoiding page reloading between views), you can implement it as a dynamic table.

Dynamic Tables

The only way to make data points of a table dynamically updatable in backward-compatible browsers is to turn those data points into text (or `TEXTAREA`) objects. The approach to this implementation is different from the static table because it involves the combination of *immediate* and *deferred* scripting. Immediate scripting facilitates the building of the table framework, complete with fields for every modifiable location in the table. Deferred scripting enables users to make choices from other interface elements, causing a new set of variable data to appear in the table's fields.

Listing 49-2 turns the preceding static calendar into a dynamic one by including controls that enable the user to select a month and year to display in the table. As testament to the support for absolute backward compatibility, a button triggers the redrawing of the calendar contents, rather than `onChange` event handlers in the `SELECT` elements. A bug in NN2 for Windows caused that event not to work for the `SELECT` object.

Form controls aside, the look of this version is quite different from the static calendar. Compare the appearance of the dynamic version shown in Figure 49-2 against the static version in Figure 49-1.

Figure 49-2: Dynamic calendar generated by Listing 49-2

When you first load Listing 49-2, it creates an empty table. Even so, it may take a while to load, depending on the platform of your browser and the speed of your computer's processor. This page creates numerous text objects. An `onLoad` event handler in the `Body` definition also could easily set the necessary items to load the current month.

From a cosmetic point of view, the dynamic calendar may not be as pleasing as the static one in Figure 49-1. Several factors contribute to this appearance.

From a structural point of view, creating a table that can accommodate any possible layout of days and dates that a calendar may require is essential. That means a basic calendar consisting of six rows of fields. For many months, the last row remains completely empty. But because the table definition must be fixed when the page loads, this layout cannot change on the fly.

The more obvious cosmetic comparison comes from the font and alignment of data in text objects. Except for capabilities of browsers capable of using style sheets, you're stuck with what the browser presents in both categories. In the static version, you can define different font sizes and colors for various fields, if you want (such as coloring the entry for today's date). Not so in text objects in a backward-compatible program.

This cosmetic disadvantage, however, is a boon to functionality and interactivity on the page. Instead of the user being stuck with an unchanging calendar month, this version includes pop-up menus from which the user can select a month and year of choice. Clicking the Update Calendar button refills the calendar fields with data from the selected month.

One more disadvantage to this dynamic table surfaces, however: All text objects can be edited by the user. For many applications, this capability may not be a big deal. But if you're creating a table-based application that encourages users to enter values in some fields, be prepared (in other words, have event handlers in place) to either handle calculations based on changes to any field or to alert users that the fields cannot be changed (and restore the correct value).

Hybrids

It will probably be the rare scripted table that is entirely dynamic. In fact, the one in Figure 49-2 is a hybrid of static and dynamic table definitions. The days of the week at the top of each column are hard-wired into the table as static elements. If your table design can accommodate both styles, implement your tables that way. The fewer the number of text objects defined for a page, the better the performance for rendering the page, and the less confusion for the page's users.

Dynamic HTML Tables

If you have the luxury of developing for IE4+ and/or NN6, you have all the resources of the `TABLE` and related element objects, as described in Chapter 27. The resulting application will appear to be much more polished, because not only does your content flow inside a table (which you can style to your heart's delight), but the content is dynamic within the table.

Listing 49-3 blends the calendar calculations from the earlier two calendar versions with the powers of IE4+/Windows and W3C DOMs. A change to a requested calendar month or year instantly redraws the body of the table, without disturbing the rest of the page (see Figure 49-3).

Figure 49-3: DHTML table

Basic date calculations are identical to the other two versions. Because this page has to be used with more modern browsers, it can use a genuine `Array` object for the month names. Also, the way the table must be constructed each time is very different from two previous versions. In this version, the script creates new table rows, creates new cells for those rows, and then populates those cells with the date numbers. Repeat loop logic is quite different, relying on a combination of `while` and `for` loops to get the job done.

Other features made possible by more modern browsers include automatic population of the list of available years. This page will never go out of style (unless browsers in 2050 no longer use JavaScript). There is also more automation in the triggers of the function that populates the table.

Further Thoughts

The best deployment of an interactive calendar requires the kind of Dynamic HTML currently available in IE4+/Windows and W3C DOMs. Moreover, the cells in those DOMs can receive mouse events so that a user can click a cell and it will highlight perhaps in a different color or display some related, but otherwise hidden, information.

A logical application for such a dynamic calendar would be in a pop-up window or frame that lets a user select a date for entry into a form date field. It eliminates typing in a specific date format, thereby ensuring a valid date entry every time. Without DHTML, you can create a static version of the calendar that renders the numbers in the calendar cells as HTML links. Those links can use a javascript: URL to invoke a function call that sets a date field in the main form.

Note

The dynamic calendar in Listing 49-2 assumes that the browser treats like-named text boxes in a form as an array of fields. While this is true in all versions of NN, IE3 does not follow this behavior. To accommodate this anomaly, you must modify the script to assign unique names to each field (with an index number as part of the name) and use the `eval()` function to assist looping through the fields to populate them. On the CD-ROM is Listing 49-2b, which is a cross-compatible version of the dynamic calendar.

Application: A Lookup Table

One of the first ideas that intrigued me about JavaScript was the notion of delivering CGI-like functionality along with an HTML document. On the Web, numerous, small data collections currently require CGI scripting and a back-end database engine to drive them. Of course, not everyone who has information to share has access to the server environment (or the expertise) to implement such a solution. JavaScript provides that power.

A Serverless Database

Before you get too carried away with the idea of letting JavaScript take the place of your SQL database, you need to recognize several limitations that prevent JavaScript from being a universal solution. First, any database that you embed into an HTML document is read-only. Although you can script an interface and lookup routines for the user, no provisions are available for writing revised information back to the server, if that is your intention.

A second consideration is the size of the data collection. Unlike databases residing on servers, the entire JavaScript database (or subset you define for inclusion into a single HTML document) must be downloaded to the user's browser before the user can work with the data. As a point of reference, think about image files. At less than 56 Kbps, how large an image file would you tolerate downloading? Whatever that limit may be (anywhere from 10 to 35K, depending on your patience) is what your database size limit should be. For many special-purpose collections, this is plenty of space, assuming one byte per character. Unlike what happens when the user downloads an embedded image file, the user doesn't see special statusbar messages about your database: To the browser, these messages are all part of the HTML coming in with the document.

50

CHAPTER

In This Chapter

Severless data
collection lookup

Data-entry validation

The kind of data I'm talking about here is obviously text data. That's not to say you can't let your JavaScript-enhanced document act as a front end to data files of other types on your server. The data in your embedded lookup table can be URLs to images that get swapped into the page as needed.

The Database

As I was thinking about writing a demonstration of a serverless database, I encountered a small article in the *Wall Street Journal* that related information I had always suspected. The Social Security numbers assigned to virtually every U.S. citizen are partially coded to indicate the state in which you registered for your Social Security number. This information often reveals the state in which you were born (another study indicates that two-thirds of U.S. citizens live their entire lives in the same state). The first three digits of the nine-digit number comprise this code.

When the numbering system was first established, each state was assigned a block of three-digit numbers. Therefore, if the first three digits fall within a certain range, the Social Security Administration has you listed as being registered in the corresponding state or territory. I thought this would be an interesting demonstration for a couple of reasons: first, the database is not that large, so it can be easily embedded into an HTML document without making the document too big to download, even on slow Internet connections; second, it offers some challenges to data-entry validation, as you see in a moment.

**Note**

Before young people from populous states write to tell me that their numbers are not part of the database, let me emphasize that I am well aware that several states have been assigned number blocks not reflected in the database. This example is only a demonstration of scripting techniques, not an official Social Security Administration page.

The Implementation Plan

For this demonstration, all I started with was a printed table of data. I figured that the user interface for this application would probably be very plain: a text field in which the user can enter a three-digit number, a clickable button to initiate the search, and a text field to show the results of the lookup. Figure 50-1 shows the page. Pretty simple by any standards.

Given that user interface (I almost always start a design from the *interface* — how my page's users will experience the information presented on the page), I next planned the internals. I needed the equivalent of two tables: one for the numeric ranges, and one for the state names. Because most of the numeric ranges are contiguous, I could get by with a table of the high number of each range. This meant that the script would have to trap elsewhere for the occasional numbers that fall outside of the table's ranges — the job of data validation.

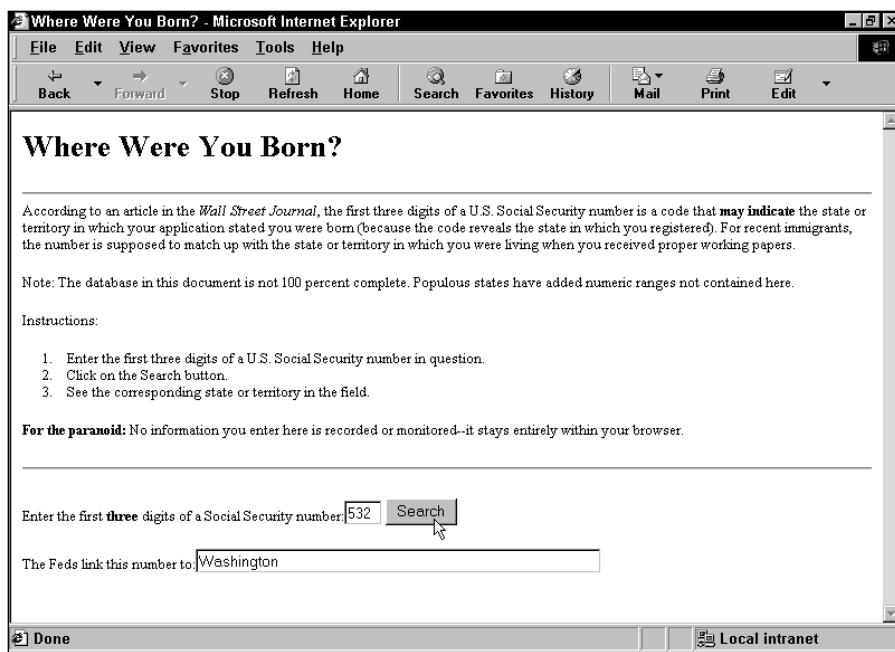

Figure 50-1: The Social Security number lookup page

Because the two tables were so closely related to each other, I had the option of creating two separate arrays, so that any given index value would correspond to both the numeric and state name entries in both tables (*parallel arrays*, I call them). The other option was to create a two-dimensional array (see Chapter 37), in which each array entry has data points for both the number and state name. For purposes of demonstration to first-time database builders, I decided to stay with two parallel arrays. This method makes visualizing how the lookup process works with two separate arrays a little easier.

The Code

The HTML document starts normally through the definition of the document title:

```
<HTML>
<HEAD>
<TITLE>Where Were You Born?</TITLE>
```

Because I chose to use the Array object of NN3 and IE3/J2, I added a separate script segment to gracefully handle the click of the button for those who landed at this page with an earlier scriptable browser. By putting a `<SCRIPT LANGUAGE="JavaScript">` tag ahead of the `<SCRIPT LANGUAGE="JavaScript1.1">` tag, I ensure that the one function triggered by the button is treated appropriately for all scriptable browsers:

```

<SCRIPT LANGUAGE="JavaScript">
<!-- hide from non-scriptable browsers
function search(form) {
    alert("This page a more recent browser version.")
}
// end hiding -->
</SCRIPT>

```

Immediately after the starting `<SCRIPT>` tag comes the HTML beginning comment, so that most non-JavaScript-enabled browsers ignore all statements between the start and end comments (just before the `</SCRIPT>` tag). Failure to do this results in all code lines appearing in non-JavaScript browsers as regular HTML text.

Now we come to the JavaScript 1.1-level scripts, which handle everything from building the tables of data to looking up data later in response to a button click. I begin by creating the first array for the top numbers of each entry's numeric range.

In this application, you will see that I place utility function definitions close to the top of the script sections and put any action-oriented scripts (functions acting in response to event handlers) closer to the bottom of the script sections. My preference is to have all dependencies resolved before the script needs them. This philosophy carries over from the logic that dictates putting as many scripts in the Head as possible, so that even if the user (or network) should interrupt downloading of a page before every line of HTML reaches the browser, any user interface element relying on scripts will have those scripts loaded and ready to go. The order of functions in this example is not critical, because as long as they all reside in the Head section, they are defined and loaded by the time the field and button appear at the bottom of the page. But after I develop a style, I find it easier to stick with it—one less matter to worry about while scripting a complex application.

After creating an array (named `ssn`) with 57 empty slots, the script populates all 57 data points of the array, starting with the first entry going into the slot numbered 0. These data numbers correspond to the top end of each range in the 57-entry table. For example, any number greater than 3 but less than or equal to 7 falls into the range of the second data entry of the array (`ssn[1]`).

```

<SCRIPT LANGUAGE="JavaScript1.1">
<!-- hide from non-scriptable browsers

// create array that lists the top end of each numeric range
var ssn = new Array(57)
ssn[0] = 3
ssn[1] = 7
ssn[2] = 9
ssn[3] = 34
ssn[4] = 39
ssn[5] = 49
ssn[6] = 134
ssn[7] = 158
ssn[8] = 211
ssn[9] = 220
ssn[10] = 222
ssn[11] = 231
ssn[12] = 236
ssn[13] = 246
ssn[14] = 251
ssn[15] = 260

```

```
ssn[16] = 267
ssn[17] = 302
ssn[18] = 317
ssn[19] = 361
ssn[20] = 386
ssn[21] = 399
ssn[22] = 407
ssn[23] = 415
ssn[24] = 424
ssn[25] = 428
ssn[26] = 432
ssn[27] = 439
ssn[28] = 448
ssn[29] = 467
ssn[30] = 477
ssn[31] = 485
ssn[32] = 500
ssn[33] = 502
ssn[34] = 504
ssn[35] = 508

ssn[46] = 544
ssn[47] = 573
ssn[48] = 574
ssn[49] = 576
ssn[50] = 579
ssn[51] = 580
ssn[52] = 584
ssn[53] = 585
ssn[54] = 586
ssn[55] = 599
ssn[56] = 728
```

I do the same for the array containing the states and territory names. Both of these array populators seem long but pale in comparison to what you would have to do with a database of many kilobytes. Unfortunately, JavaScript doesn't give you the power to load existing data files into arrays (but see the recommendations at the end of the chapter), so any time you want to embed a database into an HTML document, you must go through this array-style assignment frenzy:

```
// create parallel array listing all the states/territories
// that correspond to the top range values in the first array
var geo = new Array(57)
geo[0] = "New Hampshire"
geo[1] = "Maine"
geo[2] = "Vermont"
geo[3] = "Massachusetts"
```

```
geo[4] = "Rhode Island"  
geo[5] = "Connecticut"  
geo[6] = "New York"  
geo[7] = "New Jersey"  
geo[8] = "Pennsylvania"  
geo[9] = "Maryland"  
geo[10] = "Delaware"  
geo[11] = "Virginia"  
geo[12] = "West Virginia"  
geo[13] = "North Carolina"  
geo[14] = "South Carolina"  
geo[15] = "Georgia"  
geo[16] = "Florida"  
geo[17] = "Ohio"  
geo[18] = "Indiana"  
geo[19] = "Illinois"  
geo[20] = "Michigan"  
geo[21] = "Wisconsin"  
geo[22] = "Kentucky"  
geo[23] = "Tennessee"  
geo[24] = "Alabama"  
geo[25] = "Mississippi"  
geo[26] = "Arkansas"  
geo[27] = "Louisiana"  
geo[28] = "Oklahoma"  
geo[29] = "Texas"  
geo[30] = "Minnesota"  
geo[31] = "Iowa"  
geo[32] = "Missouri"  
geo[33] = "North Dakota"  
geo[34] = "South Dakota"  
geo[35] = "Nebraska"  
geo[36] = "Kansas"  
geo[37] = "Montana"  
geo[38] = "Idaho"  
geo[39] = "Wyoming"  
geo[40] = "Colorado"  
geo[41] = "New Mexico"  
geo[42] = "Arizona"  
geo[43] = "Utah"  
geo[44] = "Nevada"  
geo[45] = "Washington"  
geo[46] = "Oregon"  
geo[47] = "California"  
geo[48] = "Alaska"  
geo[49] = "Hawaii"  
geo[50] = "District of Columbia"  
geo[51] = "Virgin Islands"  
geo[52] = "Puerto Rico"  
geo[53] = "New Mexico"  
geo[54] = "Guam, American Samoa, N. Mariana Isl., Philippines"  
geo[55] = "Puerto Rico"  
geo[56] = "Long-time or retired railroad workers"
```

Now comes the beginning of the data validation functions. Under control of a master validation function shown in a minute, the `stripZeros()` function removes any leading 0s that the user may have entered. Notice that the instructions tell the user to enter the first three digits of a Social Security number. For 001 through 099, that means the numbers begin with one or two 0s. JavaScript, however, treats any numeric value starting with 0 as an octal value. Because I have to do some numeric comparisons for the search through the `ssn[]` array, the script must make sure that the entries (which are strings to begin with, coming as they do from text objects) can be converted to decimal numbers. The `parseInt()` function, with the all-important second parameter indicating Base 10 numbering, does the job. But because the remaining validations assume a string value, the integer is reconverted to a string value before it is returned.

```
// **BEGIN DATA VALIDATION FUNCTIONS**
// JavaScript sees numbers with leading zeros as octal values,
// so strip zeros
function stripZeros(inputStr) {
    return parseInt(inputStr, 10).toString()
}
```

The next three functions are described in full in Chapter 43, which discusses data validation. In the last function, a copy of the input value is converted to an integer to enable the function to make necessary comparisons against the boundaries of acceptable ranges.

```
// general purpose function to see if an input value has been entered
// at all
function isEmpty(inputStr) {
    if (inputStr == null || inputStr == "") {
        return true
    }
    return false
}

// general purpose function to see if a suspected numeric input
// is a positive integer
function isNumber(inputStr) {
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = inputStr.charAt(i)
        if (oneChar < "0" || oneChar > "9") {
            return false
        }
    }
    return true
}

// function to determine if value is in acceptable range for this
// application
function inRange(inputStr) {
    num = parseInt(inputStr)
    if (num < 1 || (num > 586 && num < 596) || (num > 599 &&
        num < 700) || num > 728) {
        return false
    }
    return true
}
```

The master validation controller function (named `isValid()` in this application) is also covered in depth in Chapter 43. A statement that wants to know if it should proceed with the lookup process calls this function. If any one validation test fails, the function returns `false`, and the search does not proceed.

```
// Master value validator routine
function isValid(inputStr) {
    if (isEmpty(inputStr)) {
        alert("Please enter a number into the field before
clicking the button.")
        return false
    } else {
        if (!isNumber(inputStr)) {
            alert("Please make sure entries are numbers only.")
            return false
        } else {
            if (!inRange(inputStr)) {
                alert("Sorry, the number you entered is not part of our
database. Try another three-digit number.")
                return false
            }
        }
    }
    return true
}
// **END DATA VALIDATION FUNCTIONS**
```

The `search()` function is invoked by two different event handlers (and indirectly by a third). The two direct calls come from the input field's `onChange` event handler and the Search button's `onClick` event handler. The handler passes a reference to the form, which includes the button and both text objects.

To search the database, the script repeatedly compares each succeeding entry of the `ssn[]` array against the value entered by the user. For this process to work, a little bit of preliminary work is needed. First comes an initialization of a variable, `foundMatch`, which comes into play later. Initially set to `false`, the variable is set to `true` only if there is a successful match—information you need later to set the value of the result text object correctly for all possible conditions.

```
// Roll through ssn database to find index;
// apply index to geography database
function search(form) {
    var foundMatch = false
    var inputStr = stripZeros(form.entry.value)
    if (isValid(inputStr)) {
        inputValue = inputStr
        for (var i = 0; i < ssn.length; i++) {
            if (inputValue <= ssn[i]) {
                foundMatch = true
                break
            }
        }
    }
    form.result.value = (foundMatch) ? geo[i] : ""
    form.entry.focus()
    form.entry.select()
}
```

Next comes all the data preparation. After the entry is passed through the zero stripper, a copy is dispatched to the master validation controller, which, in turn, sends copies to each of its special-purpose minions. If the master validator detects a problem from the results of any of those minions, it returns `false` to the condition that wants to know if the input value is valid. Should the value not be valid, processing skips past the `for` loop and proceeds immediately to an important sequence of three statements.

The first is a conditional statement that relies on the value of the `foundMatch` variable that was initialized at the start of this function. If `foundMatch` is still `false`, that means that something is wrong with the entry and it cannot be processed. To prevent any incorrect information from appearing in the result field, that field is set to an empty string if `foundMatch` is `false`. The next two statements set the focus and selection to the entry field, inviting the user to try another number.

On the other hand, if the entry is a valid number, the script finally gets to perform its lookup task. Looping through every entry of the `ssn[]` array starting with entry 0 and extending until the loop counter reaches the last item (based on the array's length property), the script compares the input value against each entry's value. If the number is less than or equal to a particular entry, the value of the loop counter (`i`) is frozen, the `foundMatch` variable is set to `true`, and execution breaks out of the `for` loop.

This time through the conditional expression, with `foundMatch` being `true`, the statement plugs the corresponding value of the `geo[]` array (using the frozen value of `i`) into the result field. Focus and selection are set to the entry field to make it easy to enter another value.

Browsers that recognize keyboard events benefit by allowing the search to be initiated if the user presses the Enter key after entering a number. An `onKeyPress` event handler for the input text box invokes the `searchOnReturn()` function. This function employs cross-browser event parsing to find out if the Return key had been pressed while the text pointer was in the text box. If so, then the `search()` function, described earlier, is asked to do its job. Any characters other than the Return key are allowed to pass unchanged to the input box.

```
// start search if input field receives a Return character
function searchOnReturn(form, evt) {
    evt = (evt) ? evt : (window.event) ? window.event : ""
    if (evt) {
        var theKey = (evt.which) ? evt.which : evt.keyCode
        if (theKey == 13) {
            search(form)
            return false
        }
    }
    return true
}
// end code hiding -->
</SCRIPT>
</HEAD>
```

The balance of the code is the Body part of the document. The real action takes place within the Form definition.

```
<BODY>
<H1>Where Were You Born?</H1>
<HR>
```

According to an article in the <CITE>Wall Street Journal</CITE>, the first three digits of a U.S. Social Security number is a code for the state or territory in which your application stated you were born. For recent immigrants, the number is supposed to match up with the state or territory in which you were living when you received proper working papers.<P>

Note: The database in this document is not 100 percent complete. Populous states have added numeric ranges not contained here.<P>

Instructions:

Enter the first three digits of a U.S. Social Security number in question.

Click on the Search button.

See the corresponding state or territory in the field.

<P>For the paranoid: No information you enter here is recorded or monitored—it stays entirely within your browser.<P>

<HR>

The form's onSubmit event handler is set to prevent accidental submission (or pseudo-submission, because no ACTION attribute is specified for the form) that IE/Mac does from any form's text box (other browsers submit on Return from only a single-field form). Each of the text objects is sized to fit the expected data. A handful of event handlers invoke the search() function (directly and indirectly), passing a reference to the form as a parameter.

```
<FORM onSubmit="return false">
Enter the first <B>three</B> digits of a Social Security number:<INPUT
TYPE="text" NAME="entry" SIZE=4 onKeyPress="return searchOnReturn(this.form,
event)" onChange="search(this.form)">
<INPUT TYPE="button" VALUE="Search" onClick="search(this.form)">
<P>
The Feds link this number to:<INPUT TYPE="text" NAME="result" SIZE=50>
</FORM>
</BODY>
</HTML>
```

Further Thoughts

If I were doing this type of application for production purposes, I would turn each pairing of range high number and geographical location into separate objects and store the objects in an array. Making that technique work requires one extra function and a different way of populating the data. The following is an example using the same variable names as the preceding listing:

```
// specify an array entry with two items
function dataRecord(ssn, geo) {
    this.ssn = ssn
    this.geo = geo
    return this
}
```

```
// initialize basic array
var numberState = new Array(57)

// populate main array with smaller arrays
numberState[0] = new dataRecord(3, "New Hampshire")
numberState[1] = new dataRecord(7, "Maine")
numberState[2] = new dataRecord(9, "Vermont")
```

The other changes (marked in boldface) occur in the `search()` function, which must address this data in a slightly different way than it did before:

```
function search(form) {
    var foundMatch = false
    var inputStr = stripZeros(form.entry.value)
    if (isValid(inputStr)) {
        inputValue = inputStr
        for (var i = 0; i < numberState.length; i++) {
            if (inputValue <= numberState[i].ssn) {
                foundMatch = true
                break
            }
        }
        form.result.value = (foundMatch) ? numberState[i].geo : ""
        form.entry.focus()
        form.entry.select()
    }
}
```

All references to data are to the `numberState[]` array and properties of its objects (either `ssn` or `geo`). With the data for each record arranged in a comma-delimited fashion, it may be easier to transfer data exported from an existing database to your script with less copying and pasting or dragging and dropping.

Another possibility would be to use JavaScript's capability to load `.js` files that have the arrays already populated or have variables preloaded with comma-delimited values. By using the `string.split()` method (Chapter 34), you can easily assign data in this format to an array.

From a user interface perspective, the `searchOnReturn()` function can do more with the event object. For instance, it could filter data entry so that only numbers ever reach the input text field. You would still want to perform the data-entry validation in case someone were to paste some non-numeric text into the text box.

I truly believe that serverless data lookups offer a great opportunity to many creative JavaScripters.

51

CHAPTER

Application: A “Poor Man’s” Order Form

I hesitate to call the application described in this chapter an “order form” because it is not in any way intended for use as a client-side shopping cart or some of the more advanced e-commerce applications you see on the Web. No, the goal here is to demonstrate how JavaScript can be used to assist users with column-and-row arithmetic, very much like the kinds of arithmetic needed to calculate the total for an order of goods.

While this order form is not linked to any particular online catalog, some or all of it can be used as a piece for a small e-commerce site. The form in the example here requires that users input product descriptions and prices, but there is no reason that a client-side JavaScript shopping cart can’t accumulate the shopper’s choices from catalog pages, and then present them in an order form with product descriptions and prices hard-wired into the table. There still are entry boxes for quantity and selecting local sales tax rates. But all the arithmetic products and sums are calculated quickly on the client with JavaScript.

Along the way, you should also discover how to design code—more specifically, JavaScript data structures—in such a way that they are easily editable by non-scripters who are responsible for updating the embedded data. Therefore, even if you prefer to leave professional e-commerce order processing to server CGIs, you may still pick up a scripting tip or two from this “poor man’s” version of an order form.

Defining the Task

I doubt that any two order forms on the Web are executed precisely the same way. Much of the difference has to do with the way a CGI program on the server wants to receive the data on its way to an order-entry system or database. The rest has

In This Chapter

Live math on table rows and columns

Number formatting

Code reusability

Form HTML and Scripting

Because this form is generated as the document loads, JavaScript writes most of the document to reflect the variable choices made in the reusable parts of the script. In fact, in this example, only the document heading is hard-wired in HTML.

The script uses a few JavaScript facilities that aren’t available in the earliest browsers, so you have to guard against browsers of other levels reaching this page and receiving script errors when `document.write()` statements fail to find functions defined inside JavaScript 1.1 language script tags. As part of this defense, I defined a JavaScript 1.0 function, called `initialize()`, ahead of any other script. This function is called later in the Body. Because both types of browsers can invoke this function, the Head portion of this document contains an `initialize()` function in both JavaScript 1.0 and JavaScript 1.1 script tags. For JavaScript 1.0 browsers, the function displays a message alerting the user that this form requires a more recent browser. Your message could be more helpful and perhaps even provide a link to another version of the order form. In the JavaScript 1.1 portion, the `initialize()` function is empty, sitting ready to catch and ignore the call made by the document:

```
<HTML>
<HEAD>
<TITLE>Scripted Order Form</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!--
// displays notice for non-JavaScript 1.1 browsers
function initialize() {
    document.write("This page a more recent browser version.")
}
// -->
</SCRIPT>
```

Global adjustments

The next section is the start of the JavaScript 1.1-level statements and functions that do most of the work for this document. The script begins by initializing three very important global variables. This location is where the author defining the details for the order form also enters information about the column headings, column widths, and number of data entry rows.

```
<SCRIPT LANGUAGE="JavaScript1.1">
<!--
// ** BEGIN GLOBAL ADJUSTMENTS ** //
// Order form columns and rows specifications
// **Column titles CANNOT CONTAIN PERIODS
var columnHeads = "Qty,Stock#,Description,Price,Total".split(",")
var columnWidths = "3,7,20,7,8".split(",")
var numberOfRows = 5
```

The first two assignment statements perform double duty. Not only do they provide the location for customized settings to be entered by the HTML author, but they use the `string.split()` method to literally create arrays out of their series

of comma-delimited strings. At first, this may seem to be a roundabout way to generate an array, because you can also create the array directly with:

```
var columnHeads = new Array("Qty", "Stock", ...)
```

But the way shown here minimizes the possibility of goofing up the quotes and commas when modifying the data, especially if modification might be attempted by a non-scripter.

So much of the repetitive work to come in this application is built around arrays that it will prove to be extraordinarily convenient to have the column title names and column widths in parallel arrays. The number-of-rows value also plays a role in not only drawing the form, but calculating it as well.

Notice the caveat about periods in column heading strings. You will soon see that these column names are assigned as text object names, which, in turn, are used to build object references to text boxes. Object names cannot have periods in them, so for these column headings to perform their jobs, you have to leave periods out of their names.

As part of the global adjustment area, the `extendRow()` method requires knowledge about which columns are to be multiplied to reach a total for any row:

```
// data entry row math
function extendRow(form, rowNum) {
    // **change 'Qty' and 'Price' to match your column names
    var rowSum = form.Qty[rowNum].value * form.Price[rowNum].value
    // **change 'Total' to match your corresponding column name
    form.Total[rowNum].value = formatNum(rowSum, 2)
}
```

This example uses the `Qty`, `Price`, and `Total` fields for math calculations. Those field names are inserted into the references within this function. To calculate the total for each row, the function receives the form object reference and the row number as parameters. As described later, the order form is generated as a kind of array. Each field in a column intentionally has the same name. This scheme enables scripts to access a given field in that column by row number when using the row number as an index to the array of objects bearing the same name. For example, for the first row (row 0), you calculate the total by multiplying the quantity field of row 0 (`form.Qty[0].value`) times the price field of row 0 (`form.Price[0].value`). You then format that value to two places to the right of the decimal and plug that number into the value of the total field for row 0 (`form.Total[0].value`).

The final place where you have to worry about customized information is in the function that adds up the total columns. The function must know the name that you assigned to the total column:

```
function addTotals(form) {
    var subTotal = 0
    for (var i = 0; i < numberOfRows; i++) {
        // **change 'Total' in both spots to match your column name
        subTotal += (form.Total[i].value != "") ?
            parseFloat(form.Total[i].value) : 0
    }
    form.subtotal.value = formatNum(subTotal, 2)
    form.tax.value = formatNum(getTax(form, subTotal), 2)
    form.total.value = "$" + formatNum((parseFloat(form.subtotal.value) +
        parseFloat(form.tax.value) + parseFloat(form.shipping.value)), 2)
}
// ** END GLOBAL ADJUSTMENTS ** //
```

The `addTotals()` function receives the form reference as a parameter, which it uses to read and write data around the form. The first task is to add up the values of the total fields from each of the data-entry rows. Here you need to be specific about the name you assign to that column. To keep code lines to a minimum, you use a conditional expression inside the `for` loop to make additions to the `subTotal` amount only when a value appears in a row’s total field. Because all values from text fields are strings, you use `parseFloat()` to convert the values to floating-point numbers before adding them to the `subTotal` variable.

Three more assignment statements fill in the subtotal, tax, and total fields. The subtotal is nothing more than a formatted version of the amount reached at the end of the `for` loop. The task of calculating the sales tax is passed off to another function (described in a following section), but its value is also formatted before being plugged into the sales tax field. For the grand total, you add floating-point-converted values of the subtotal, tax, and shipping fields before slapping a dollar sign in front of the result. Even though the three fields contain values formatted to two decimal places, any subsequent math on such floating-point values incurs the minuscule errors that send formatting out to sixteen decimal places. Thus, you must reformat the results after the addition.

Do the math

As you can see from Figure 51-1, the user interface for entering the sales tax is a pair of SELECT elements. This type of interface minimizes the possibility of users entering the value in all kinds of weird formats that, in some cases, would be impossible to parse. The function that calculates the sales tax of the subtotal looks to these select objects for their current settings.

```
function getTax(form,amt){
    var chosenPercent = form.percent[form.percent.selectedIndex].value
    var chosenFraction = form.fraction[form.fraction.selectedIndex].value
    var rate = parseFloat(chosenPercent + "." + chosenFraction) / 100
    return amt * rate
}
```

After receiving the form object reference and subtotal amount as parameters, the function reads the two values chosen in the SELECT elements. The string `value` properties of the SELECT objects are temporarily stored in local variables. To arrive at the actual rate, you concatenate the two portions of the string (joined by an artificial decimal point) and `parseFloat()` the string to get a number that you can then divide by 100. The product of the subtotal times the rate is returned to the calling statement (in the preceding `addTotals()` function).

All of the calculation that ripples through the order form is controlled by a single `calculate()` function:

```
function calculate(form,rowNum) {
    extendRow(form,rowNum)
    addTotals(form)
}
```

This function is called by any object that affects the total of any row. Such a request includes both the form object reference and the row number. This information lets the single affected row, and then the totals column, be recalculated. Changes to some objects, such as the sales tax SELECT objects, affect only the

totals column, so they will call `addTotals()` function directly rather than this function (the rows don't need recalculation).

Number formatting, as explained in Chapter 35, is a detail that scripters must handle themselves (unless you are designing for IE5.5+ and NN6+, which include the `number.toFixed()` method for number formatting). We can borrow the formatting code from Chapter 35, and use it here as-is:

```
function formatNum(expr,decplaces) {
    var str = (Math.round(parseFloat(expr) *
        Math.pow(10,decplaces))).toString()
    while (str.length <= decplaces) {
        str = "0" + str
    }
    var decpoint = str.length - decplaces
    return str.substring(0,decpoint) + "." +
        str.substring(decpoint,str.length)
}
```

Being able to pick up this function from a different application should reinforce the advantage to writing functions to be as generalizable as possible. Rather than building page-specific references into the formatting function, it accepts parameters that could come from anywhere. Page specifics are left to another function that deals with reading and writing text box values.

Cooking up some HTML

As we near the end of the scripting part of the document's Head section, we come to two functions that are invoked later to assemble some table-oriented HTML based on the global settings made at the top. One function assembles the row of the table that contains the column headings:

```
function makeTitleRow() {
    var titleRow = "<TR>"
    for (var i = 0; i < columnHeads.length; i++) {
        titleRow += "<TH>" + columnHeads[i] + "</TH>"
    }
    titleRow += "</TR>"
    return titleRow
}
```

The heart of the `makeTitleRow()` function is the `for` loop, which makes simple `<TH>` tags out of the text entries in the `columnHeads` array defined earlier. All this function does is assemble the HTML. A `document.write()` method in the Body puts this HTML into the document.

```
function makeOneRow(rowNum) {
    var oneRow = "<TR>"
    for (var i = 0; i < columnHeads.length; i++) {
        oneRow += "<TD ALIGN=middle><INPUT TYPE=text SIZE=" +
            columnWidths[i] + " NAME=\'" + columnHeads[i] +
            "\' onChange='calculate(this.form," + rowNum + ")'></TD>"
    }
    oneRow += "</TR>"
    return oneRow
}
```

Creating a row of entry fields is a bit more complex, but not much. Instead of assigning just a word to each cell, you assemble an entire `<INPUT>` object definition. You use the `columnWidths` array to define the size for each field (which therefore defines the width of the table cell in the column). `columnHead` values are assigned to the field’s `NAME` attribute. Each column’s fields have the same name, no matter how many rows exist. Finally, the `onChange` event handler invokes the `calculate()` method, passing the form and, most importantly, the row number, which comes into this function as a parameter (see the following section).

Some JavaScript language cleanup

The final function in the Head script is an empty function for `initialize()`. This function is the one that JavaScript 1.1-level browsers activate after the document loads into them:

```
// do nothing when JavaScript 1.1 browser calls here
function initialize() {}
//-->
</SCRIPT>
</HEAD>
<BODY>
<CENTER>
<H1>ORDER FORM</H1>
<FORM>
<TABLE BORDER=2>
<SCRIPT LANGUAGE="JavaScript">
<!--
initialize()
// -->
</SCRIPT>
```

From there, you start the `<BODY>` definition, including a simple header. You immediately go into the form and table definitions. A JavaScript script that will be run by all versions of JavaScript invokes the `initialize()` function. JavaScript 1.0-level browsers execute the `initialize()` function in the topmost version in the Head so that they display the warning message in the document’s body; JavaScript 1.1-level browsers execute the empty function you see.

Tedium lost

Believe it or not, all of the rows of data-entry fields in the table are defined by the handful of JavaScript statements that follow:

```
<SCRIPT LANGUAGE="JavaScript1.1">
document.write(makeTitleRow())
// order form entry rows
for (var i = 0; i < numberOfRows; i++) {
    document.write(makeOneRow(i))
}
```

The first function to be called is the `makeTitleRow()` function, which returns the HTML for the table’s column headings. Then a very simple `for` loop writes as many rows of the field cells as defined in the global value near the top of the document. Notice how the index of the loop, which corresponds to the row number, is

passed to the `makeOneRow()` function, so that it can assign that row number to its relevant statements. Therefore, these few statements generate as many entry rows as you need.

Tedium regained

What follows in the script writes the rest of the form to the screen. To make these fields as intelligent as possible, the scripts must take the number of columns into consideration. A number of empty-space cells must also be defined (again, calculated according to the number of columns). Finally, the code-consuming `SELECT` element definitions must also be in this segment of the code.

```
// order form footer stuff (subtotal, sales tax, shipping, total)
var colSpacer = "<TR><TD COLSPAN=" +
    (columnWidths.length - 2) + "></TD>"
document.write(colSpacer)
document.write("<TH>Subtotal:</TH>")
document.write("<TD><INPUT TYPE=text SIZE=" +
    columnWidths[columnWidths.length - 1] + " NAME=subtotal></TR>")
document.write("<TR><TD COLSPAN=" +
    (columnWidths.length - 3) + "></TD>")
var tax1 = "<SELECT NAME=percent
onChange='addTotals(this.form)''><OPTION>0<OPTION>1<OPTION>2<OPTION>3"
tax1 += "<OPTION VALUE=1>1<OPTION VALUE=2>2<OPTION VALUE=3>3"
tax1 += "<OPTION VALUE=4>4<OPTION VALUE=5>5<OPTION VALUE=6>6"
tax1 += "<OPTION VALUE=7>7<OPTION VALUE=8>8<OPTION VALUE=9>9"
tax1 += "</SELECT>"
var tax2 = "<SELECT NAME=fraction onChange='addTotals(this.form)''>"
tax2 += "<OPTION VALUE=0>00<OPTION VALUE=25>25"
tax2 += "<OPTION VALUE=5>50<OPTION VALUE=75>75</SELECT>"
document.write("<TH ALIGN=RIGHT>" + tax1 + "." + tax2 + "%</TH>")
document.write("<TH ALIGN=RIGHT>Sales Tax:</TH>")
document.write("<TD><INPUT TYPE=text SIZE=" +
    columnWidths[columnWidths.length - 1] + " NAME=tax VALUE=0.00></TR>")
document.write(colSpacer)
document.write("<TH>Shipping:</TH>")
document.write("<TD><INPUT TYPE=text SIZE=" +
    columnWidths[columnWidths.length - 1] + " NAME=shipping VALUE=0.00
onChange='addTotals(this.form)''></TR>")
document.write(colSpacer)
document.write("<TH>Total:</TH>")
document.write("<TD><INPUT TYPE=text SIZE=" +
    columnWidths[columnWidths.length - 1] + " NAME=total></TR>")
</SCRIPT>

</TABLE></FORM>
</BODY>
</HTML>
```

To gain a better understanding of how the script assembles the HTML for this part of the table, start by looking at the `colSpacer` variable. This variable contains a table cell definition that must span all but the rightmost two columns. Thus, the

`COLSPAN` attribute is calculated based on the length of the `columnWidths` array (minus two for the columns we need for data). Therefore, to write the line for the subtotal field, you start by writing one of these column spacers, followed by the `<TH>` type of cell with the label in it. For the actual field, you must size it to match the fields for the rest of the column. That’s why you summon the value of the last `columnWidths` value for the `SIZE` attribute. You use similar machinations for the Shipping and Total lines of the form footer material.

In between these locations, you define the Sales Tax `SELECT` objects (and a column spacer that is one cell narrower than the other one you used). To reduce the risk of data-entry error and to allow for a wide variety of values without needing a 40-item pop-up list, I divided the choices into two components and then display the decimal point and percentage symbol in hard copy. Both `SELECT` objects trigger the `addTotals()` function to recalculate the rightmost column of the form.

Sometimes, it seems odd that you can script four lines of code to get 20 rows of a table, yet it takes twenty lines of code to get only four more complex rows of a table. Such are the incongruities of the JavaScripter’s life.

Further Thoughts

Depending on the catalog of products or services being sold through this order form, the first improvement I would make is to automate the entry of stock number and description. For example, if the list of all product numbers isn’t that large, you may want to consider dropping a `SELECT` element into each cell of the Description column. Then, after a user makes a selection, the `onChange` event handler performs a lookup through a product array and automatically plugs in the description and unit price. In any version of this form, you also need to perform data validation for crucial calculation fields, such as quantity.

In a CGI-based system that receives data from this form, individual fields do not have unique names, as mentioned earlier. All `Qty` fields, for instance, have that name. But when the form is submitted, the name-value pairs appear in a fixed order every time. Your CGI program can pull the data apart partly by field name, partly by position. The same goes for a program you may build to extract form data that is e-mailed to you rather than sent as a CGI request.

Some of the other online order forms I’ve seen include reset buttons for every row or a column of checkmarks that lets users select one or more rows for deletion or resetting. Remember that people make mistakes and change their minds while ordering online. Give them plenty of opportunity to recover easily. If getting out of jam is too much trouble, they will head for the History list or Back button, and that valued order will be, well, history.

Application: Outline-Style Table of Contents

In your Web surfing, you may have encountered sites that implement an expandable, outline type of table of contents. I've long thought that these elements were great ideas, especially for sites with lots of information. An outline, such as the Windows Explorer or text-style Macintosh Finder windows, enables the author to present a large table of contents in a way that doesn't necessarily take up a ton of page space or bandwidth. From listings of top-level entries, a user can drill down to reveal only those items of interest.

No matter how much I like the idea, however, I dislike visiting these sites. A CGI program on the server responds to each click, chews on my selection, and then sends back a completely new screen, showing my choice expanded or collapsed. After working with outlines in the operating system and outliner programs on personal computers, the delays in this processing seem interminable. It occurred to me that implementing the outline interface as a client-side JavaScript can significantly reduce the delay problem and make outlines a more viable interface to a site's table of contents. This chapter documents the process that went into an early version of the outliner, which works with most older browsers. Some newer versions are also presented.

Design Challenges

The more I looked into implementing an outline in the early scripting days, the more challenges I found ahead of me.

The first problem was making the little icons (widgets) clickable so that they respond to user mouse actions. Even though images are objects in NN3 and IE4+, NN images don't have mouse-oriented event handlers until you reach NN6

52

CHAPTER

In This Chapter

Multiple frames

Clickable images

Custom objects

Image caching

Persistent data

Dynamic HTML
positioning

(although you can make some mouse events work in some versions of NN4/Windows). Therefore, it was necessary to surround each image with a link object whose HREF attribute called a `javascript: URL` and function to do the job. This technique also helped solve the next problem.

After a user clicks an outline widget, the script must update the window or frame containing the outline to expand or collapse a portion of the outline. The original design predated dynamically updated pages of IE4 and NN6, so the entire page had to be rewritten. But to make that work, the script needed a way to represent and temporarily preserve the current state of the outline—a line-by-line rundown on whether a line was currently expanded or collapsed. If the script could save that state somewhere, the widget's link HREF attribute could summon a JavaScript function whose job is to perform a soft reload of the current page without reopening it—with the `history.go()` method. Therefore, as a user clicked a widget, the state of the outline created by that click would be generated in the script, saved, and then used to specify the expanded or collapsed state of each line as the page reloaded.

Just when I was congratulating myself on how clever I was, I realized that any attempt to save the state of the new outline in a variable was doomed: Even a soft reload restores variables to their original state. I'd have to find another way to maintain the data.

The first method I used was to store the outline state (a string of 0s and 1s, in which a 1 indicated that the item was expanded) in a text box. Text and TEXTAREA objects maintain their contents even through a document reload (but not a reopen). Although this method was convenient, it was ugly because it meant that the field would have to be in the frame. One tactic was to make the frame a non-scrolling frame and stuff the field out of sight by pushing it to the far right with padding spaces inside a `<PRE>...</PRE>` tag.

Next, it was time to try Netscape's mechanism for storing persistent data on the client computer: the `document.cookie` property. Cookies are not unique to JavaScript. Any CGI can also store data, such as a user's login name and password for a site, in a cookie. The cookie did the trick. Information about the outline lasts in the cookie of any user's computer only as long as the browser stays running.

Another detail that I wanted to overcome was the initial delay experienced the first time a user clicked one of the collapsed widgets in the outline. At that point, only one of three icon image files had been loaded and cached in the browser. In the very first version of this application for NN2, I arranged to display all three widgets as decoration on the page to get them loaded up front. But with NN3+ and IE4+, I can precache all the widget art files and deploy them instantly when needed.

The Implementation Plan

I admit to approaching the outline technique the first time without a specific data-display goal in mind—not always the best way to go about it. In search of some logical and public domain data that I could use as an example, I came upon the tables of information about food composition (grams of protein, fat, calories, and so on) published by the U.S. government. For this demonstration, I created one HTML document containing data for two hierarchical categories of foods: peas and pickles. At the beginning of each food category, I assigned an anchor to which the text entries of the outline point.

My design for this implementation calls for two frames set up as columns (see Figure 52-1). The narrower left column houses the outline interface. After the frame-set loads, the wider right frame initially shows an introductory HTML document. Clicking any of the links in the outline changes the view of the right-hand frame from the introductory document to the food data document. A link at the bottom of the food data document enables the user to view the introductory document again in the same frame, if desired.

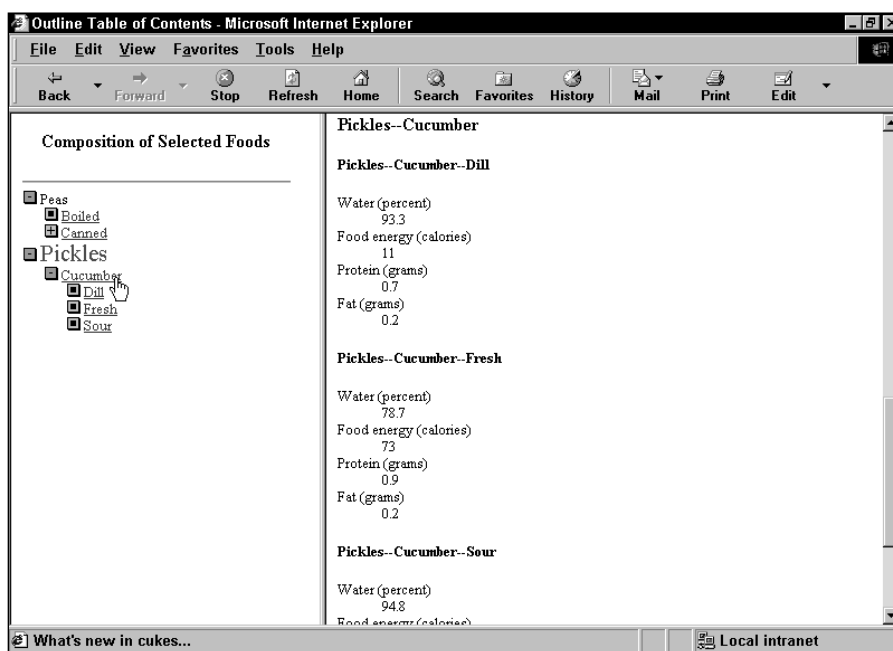

Figure 52-1: The outline in the left frame is dynamic and local.

In addition to image caching, NN3 and IE4 gave me reason to make some other improvements to the outliner over a version originally created for NN2. They include

- ♦ Adjustable indentation spacing
- ♦ Easier specification of widget art files
- ♦ Easier way to specify a target frame for the results
- ♦ Additional array field for statusbar display text

All adapter-adjustable elements appear near the top of the script to make it easy for scripters without a lot of experience to modify the application for their own sites.

For this fourth edition of the book, a couple of minor improvements make the outliner easier to modify and deploy. First, the tedious sequential numbering of items is gone. Second, performance in NN4 is greatly enhanced with the help of streamlined cookie handling.

The Code

All files for this implementation of the outline are on the CD-ROM accompanying this book, so I display here only the code for the framesetting document (`index.htm`) and the outline (`toc5.htm`). Earlier numbered filenames were used for previous editions of this book.

Setting the frames

To establish the frames, the script creates a two-column format, assigning 35 percent of the page as a column to contain the outline:

```
<HTML>
<HEAD>
<TITLE>Outline Table of Contents</TITLE>
</HEAD>

<FRAMESET COLS="35%,65%">

<NOFRAMES>
<H1>It's really cool...</H1>
<H2>...but only if you a frames-capable browser</H2>
<HR>
<A HREF="index.html">Back </A>
</NOFRAMES>

    <FRAME NAME="Frame1" SRC="toc4.htm">
    <FRAME NAME="Frame2" SRC="intro.htm">
</FRAMESET>
</HTML>
```

Because pages designed for multiple frames and JavaScript don't fare well in browsers incapable of displaying frames, a good approach is to surround HTML with a `<NOFRAMES>` tag for display to users of old browsers. You can substitute any link you like for the one shown here, which goes back to the main JavaScript page at my Web site.

The names that I assign to the two frames aren't very original or clever, but they help me remember which frame is which. Because the nature of the contents of the second frame changes (either the introductory document or the data document), I couldn't think of a good name to reflect its purpose.

Outline code

Now we come to some lengthy code for the outline (in file `toc5.htm`). Much of the code deals with managing the binary representation of the current state of the outline. For each line of the completely exploded outline, the code designates a 0 for a line that has no nested items showing and a 1 for a line that has a nested item showing. This sequence of 0s and 1s (as one string) is the road map that the script follows when redrawing the outline. Cues from the 0 and 1 settings let the script know whether it should display a nested item (if one exists) or leave that item collapsed.

To help me visualize the inner workings of these scripts, I developed a convention that calls any item with nested items beneath it a *mother*. Any nested item is that mother's *daughter*. A daughter can also be a mother if it has an item nested beneath it. You see how this plays out in the code shortly.

The food outline document starts out simply enough, with the standard opening of a JavaScript script. The first specification set apart for easy modification is the size of the indentation level in pixels.

```
<HTML>
<HEAD>
<TITLE>Food Selection Outline</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!-- begin hiding
// ** BEGIN OUTLINE AUTHOR-ADJUSTABLE SPECIFICATIONS **//

// size of horizontal indent per level
var indentPixels = 20
```

Outline level indentations are controlled by the width of a transparent image file. Indentation size is uniform throughout the outline, and the value is controlled via the `indentPixels` global variable. The image file is actually only a single pixel large, but by setting the width as needed (see the following example), it occupies a known amount of space, without affecting the font characteristics of the outline text.

Two more groups of adjustable items come next. The first group takes care of the widget images. This group is where you specify the filenames for the three widgets and provide the script with their height and width measurements:

```
// art files and sizes for three widget styles
// (all three widgets must have same height/width)
var collapsedWidget = "plus.gif"
var expandedWidget = "minus.gif"
var endpointWidget = "end.gif"
var widgetWidth = 12
var widgetHeight = 12

// Target for documents loaded when user clicks on a link.
// Specify your target frame name here.
var displayTarget = "Frame2"
```

When you design your widget art (if you don't like mine), be sure to design all three to be the same size. This practice prevents scaling of the images later.

If you deploy the outliner for your site, be sure to change the name of the frame assigned to the `displayTarget` global variable. This value eventually becomes part of the text links in the outline. If you want a click of a link to completely replace the current frameset with a different page, then specify `_top` as the display target.

Assembling outline content

The last of the easily modifiable areas defines the content of the outline. After defining the primary array (`db`), a second dimension is added to create an array of

custom objects. The `dbRecord` array (defined in the following listing) helps populate the `db` array with specifics provided in the comma-delimited statements here:

```
// Create array object containing outline content and attributes.
// To adapt outline for your use, modify this table.
// Start the array with [1], and continue without gaps to your last item.
// The order of the five parameters:
// 1. Boolean (true or false) whether _next_ item is indented.
// 2. String to display in outline entry (including <FONT> tags).
// 3. URL of link for outline entry; Use empty string ("") for no link
// 4. Integer of indentation level (0 is leftmost margin level)
// 5. String for status line onMouseOver (apostrophes require '\\')
var db = new Array()
db[db.length] = new dbRecord(true,"Peas","",0,"")
db[db.length] = new dbRecord(false,"Boiled","foods.htm#boiled",
    1,"Mmm, boiled peas...")
db[db.length] = new dbRecord(true,"Canned","foods.htm#canned",
    1,"Check out canned peas...")
db[db.length] = new dbRecord(false,"Alaska","foods.htm#alaska",
    2,"Alaska\\'s finest...")
db[db.length] = new dbRecord(false,"Low-Sodium","foods.htm#losodium",
    2,"A healthy treat...")
db[db.length] = new dbRecord(true,"<FONT COLOR=red
SIZE=+2>Pickles</FONT>","",0,"")
db[db.length] = new dbRecord(true,"Cucumber","foods.htm#cucumber",
    1,"What\\'s new in cukes...")
db[db.length] = new dbRecord(false,"Dill","foods.htm#dill",
    2,"Pucker up...")
db[db.length] = new dbRecord(false,"Fresh","foods.htm#fresh",
    2,"You\\'d prefer stale?")
db[db.length] = new dbRecord(false,"Sour","foods.htm#sour",
    2,"For sweeties...")
// add more records to complete your outline
// ** END AUTHOR-ADJUSTABLE SPECIFICATIONS **//
```

Each record consists of five items. The first item is a Boolean value, which denotes whether the item is a mother item (that is, the next item in the list is nested one level deeper). The HTML that displays in the outline comes next. This text can be multiple-word strings, or any HTML that you like (some users have assigned `` tags to show pictures instead of text). For the third item, you can insert any valid URL, whether it be to a separate site, an anchor in another document (as shown here), or even a `javascript: URL` to execute another function. If you don't want an entry in the outline to be a link—just plain, flat text—leave this third item as an empty string, as I do here for the topmost items in both categories. The fourth item is a number representing how many nested levels the item has. And finally, the last item is a string containing the text that appears in the statusbar when the user rolls the mouse over the item in the outline. Because of a quirk in the way the statusbar responds to quoted characters, any string literal character (normally preceded with a backslash) requires two backslashes (one to alert the browser of the other).

Be sure to keep the items for the `db` array in the same top-to-bottom order as you'd expect to see in a fully expanded outline. Notice that the index values of the array are automatically inserted for you: The `length` property of an array is always one more than the highest index. By inserting references to the `db.length`

property in the brackets, you instruct JavaScript to “walk the ladder” upward from zero. If you move things around the outline, however, don’t forget to adjust the indentation levels if they are affected by the content changes.

The bottom of the array creation section marks the end of the code that you need to modify after you deploy the outliner. The rest of the JavaScript code works silently for you, but if you intend to perform further customizations to the outliner, understanding how it all works will help.

On to the constructor function for the `dbRecord` entries: This function is the classic JavaScript way to build a custom object (see Chapter 41):

```
// object constructor for each outline entry
// (see object-building calls, below)
function dbRecord(mother,display,URL,indent,statusMsg){
    this.mother = mother    // is this item a parent?
    this.display = display  // text to display
    this.URL = URL         // link tied to text; no link for empty string
    this.indent = indent   // how deeply nested?
    this.statusMsg = statusMsg // descriptive text for status bar
    return this
}
```

To preload all the images into the browser’s image cache, you create new `Image` objects for each and assign the filenames to their `src` properties. Notice that these statements are not in functions, but rather execute as the page loads:

```
// pre-load all images into cache
var fillerImg = new Image(1,1)
fillerImg.src = "filler.gif"
var collapsedImg = new Image(widgetWidth,widgetHeight)
collapsedImg.src = collapsedWidget
var expandedImg = new Image(widgetWidth,widgetHeight)
expandedImg.src = expandedWidget
var endpointImg = new Image(widgetWidth,widgetHeight)
endpointImg.src = endpointWidget
```

Cookie storage

To preserve the binary digit string between redraws of the outline, this script must save the string to a place that won’t be overwritten or emptied during the document reload. The `document.cookie` fills that requirement nicely. Excerpting and adapting parts of Bill Dortch’s cookie functions (see Chapter 18), this script simplifies the writing of a cookie that disappears when the user quits the browser:

```
// ** functions that get and set persistent cookie data **
// set cookie data
var mycookie = document.cookie
function setCurrState(setting) {
    mycookie = document.cookie = "currState=" + escape(setting)
}
// retrieve cookie data
function getCurrState() {
    var label = "currState="
    var labelLen = label.length
    var cLen = mycookie.length
    var i = 0
```

```

    while (i < cLen) {
        var j = i + labelLen
        if (mycookie.substring(i,j) == label) {
            var cEnd = mycookie.indexOf(";",j)
            if (cEnd == -1) {
                cEnd = mycookie.length
            }
            return unescape(mycookie.substring(j,cEnd))
        }
        i++
    }
    return ""
}

```

A global variable is used to act as a speedy intermediary between the actual browser cookie and the functions here that need to access cookie data. The `setCurrState()` function contains a construction that you don't see much in this book, but is quite valid. Notice the three-piece assignment statement. Evaluation of this statement works from right to left. The rightmost expression concatenates a cookie label and the value passed in as a parameter to the function. Note, too, that the value is passed through the `escape()` function to properly URL-encode the data for the sake of data integrity (so that spaces and odd punctuation don't mess up the mechanism). The concatenated value is assigned to the `document.cookie` property. With the value safely dropped into the cookie (it may be just one of several name/value pairs for this domain), the value of the `document.cookie` property (which includes all name/value pairs for the domain) is assigned to the `mycookie` global variable.

Retrieving information from the cookie still requires a bit of parsing to be on the safe side. If other cookie writing were to come from the current server path, more than one cookie would be available to the current document. Parsing the entire cookie for just the portion that corresponds to the `currState` labeled cookie ensures that the script gets only the data previously saved to that label. In an earlier version of this code, the frequent access to the `document.cookie` property inside the `while` loop of `getCurrState()` wasn't a problem until the sluggish cookie reading performance of NN4 got in the way. Adapting the code to use the global variable for the repetitive parsing of the cookie value rescued the day.

The focal point

The `toggle()` function, which is pivotal in this outline scheme, receives as a parameter the index number of the `db` array element whose content the user just clicked. The purpose of this function is to grab a copy of the current outline state from the cookie, alter the binary representation of the clicked item, and feed the revised binary number back to the cookie (where it governs the display of the outline after the document reloads):

```

// **function that updates persistent storage of state**
// toggles an outline mother entry, storing new value in the cookie
function toggle(n) {
    var newString = ""
    var currState = getCurrState()

```

```

var expanded = currState.charAt(n) // of clicked item
newString += currState.substring(0,n)
newString += expanded ^ 1 // Bitwise XOR clicked item
newString += currState.substring(n+1,currState.length)
setCurrState(newString) // write new state back to cookie
}

```

To make this happen, you must extract two pieces of information before any processing: the current state from the cookie and the current setting of the clicked item. The latter is saved in a local variable named `expanded` because its 0 or 1 value represents the expanded state of that particular entry in the outline.

With those information morsels in hand, the script starts building the new binary string that gets written back to the cookie. The new string consists of three pieces: the front part of the existing string up to (but not including) the digit representing the clicked item, the changed entry, and the rest of the original string.

Changing the setting of the clicked item from a 0 to a 1, or vice versa, is necessary. Although I can implement this task a few different ways (for example, using a conditional expression or an `if...else` construction), I thought I'd exercise an operator that otherwise gets little use: the bitwise XOR operator (^). Because the values involved here are 0 and 1, performing an XOR operation with the value of 1 inverts the original value:

```

0 ^ 1 = 1
1 ^ 1 = 0

```

Okay, perhaps using an XOR operator is showing off. But the experience forced me to understand a JavaScript power that may come in handy for the future.

Selecting a widget image for an entry

At this point, the script starts defining functions to help the script statements in the Body write the HTML for the new version of the outline. The `getGIF()` function determines which of the three widget image files needs to be specified for a particular entry in the outline. The function receives the index value to the `db` array of entries created earlier in the script. As the Body script assembles the HTML for the outline, it calls this function once for each item in the outline. In return, the function provides a reference to one of three `Image` objects created earlier:

```

// **functions used in assembling updated outline**
// returns the proper GIF file name for each entry's control
function getGIF(n, currState) {
  var mom = db[n].mother // is entry a parent?
  var expanded = currState.charAt(n) // of clicked item
  if (!mom) {
    return endpointWidget
  } else {
    if (expanded == 1) {
      return expandedWidget
    }
  }
  return collapsedWidget
}

```

The decision process for this function first tries to eliminate any item that ends a mother–daughter chain. Any item that is as deeply nested as it can be (which means the item is not a mother) automatically gets the `endpointWidget` image.

Now you're left with trying to figure out whether the item in the display should get an expanded or collapsed icon. The holder of this information is the cookie. Thus, the script extracts the binary setting for the entry under scrutiny. If the cookie shows that entry to be a 1, it means that the item has nested items showing and that it should get the `expandedWidget` image; otherwise, it should get the `collapsedWidget` image. Notice that you're returning *references* to the `Image` objects, not the names of the image files.

A similar excursion through each item determines what status message is assigned to the `onMouseOver` event handler for each of the widget images. The decision tree is identical to that of the `getGIF()` function:

```
// returns the proper status line text based on the icon style
function getGIFStatus(n, currState) {
    var mom = db[n].mother // is entry a parent
    var expanded = currState.charAt(n) // of rolled item
    if (!mom) {
        return "No further items"
    } else {
        if (expanded == 1) {
            return "Click to collapse nested items"
        }
    }
    return "Click to expand nested items"
}
```

Initialize the cookie

The final task of the script running in the head is to initialize the cookie if it's empty. Using the length of the `db` array as a counter, you build a string of 0s, with one 0 for each item in the outline:

```
// initialize 'current state' storage field
if (getCurrState() == "" || getCurrState().length != (db.length)) {
    initState = ""
    for (i = 0; i < db.length; i++) {
        initState += "0"
    }
    setCurrState(initState)
}

// end -->
</SCRIPT>
</HEAD>
```

Each of those 0s in the parameter to the `setCurrState()` function corresponds to a collapsed setting for an entry in the outline. In other words, the first time the outline appears, all items are in the collapsed mode. If you modify the outline for your own use by creating your own `db` array of data, the initial state of the cookie will be set for you automatically based on the length of the `db` array.

Writing the outline

At last we reach the document Body, where the outline is assembled and written to the page. Script statements here are immediate, meaning that they execute while the page loads. I have you begin by initializing some variables that you will need in a moment. The most important variable is `newOutline`, which will be used to accumulate the contents of the outline for eventual writing to the page:

```
<BODY>
<SCRIPT LANGUAGE="JavaScript">
<!-- start
// build new outline based on the values of the cookie
// and data points in the outline data array.
// This fires each time the user clicks on a control,
// because the HREF for each one reloads the current document.
var newOutline = ""
var prevIndentDisplayed = 0
var showMyDaughter = 0
var currState = getCurrState() // get whole state string
document.write("<CENTER><H3>Composition of Selected Foods</H3>")
```

The following section is the real beef of this script: the part that assembles the HTML for the outline that displays as the document loads. In other words, this part must read the current state data from the cookie and assemble widget images and text links according to the map of expanded and collapsed items in the cookie data. These activities take place within a `for` loop that cycles through every item in the database. Each value of the `i` index refers to one listing in the `db` array. Trace the logic of one entry:

```
// cycle through each entry in the outline array
for (var i = 0; i < db.length; i++) {
  var theGIF = getGIF(i, currState) // get the image
  var theGIFStatus = getGIFStatus(i, currState) // get the status message
  var currIndent = db[i].indent // get the indent level
  var expanded = currState.charAt(i) // current state

  // display entry only if it meets one of three criteria
  if (currIndent == 0 || currIndent <= prevIndentDisplayed ||
      (showMyDaughter == 1 &&
       (currIndent - prevIndentDisplayed == 1))) {
    newOutline += "<IMG SRC=\"filler.gif\" HEIGHT = 1 WIDTH = " +
      (indentPixels * currIndent) + ">"
    newOutline += "<A HREF=\"javascript:history.go(0)\" " +
      "onMouseOver=\"window.status=\" + theGIFStatus +
      "\';return true;\" onClick=\"toggle(" + i + ");return " +
      (theGIF != endpointWidget) + "\">"
    newOutline += "<IMG SRC=\"\" + theGIF + "\" HEIGHT=" +
      widgetHeight + " WIDTH=" + widgetWidth + " BORDER=0></A>"
    if (db[i].URL == "" || db[i].URL == null) {
      newOutline += " " + db[i].display + "<BR>" // no link
    } else {
      newOutline += " <A HREF=\"" + db[i].URL + "\" TARGET=\"" +
        displayTarget + "\" onMouseOver=\"window.status=\"" +
        db[i].statusMsg + "\';return true;\">" + db[i].display +
        "</A><BR>"
    }
  }
}
```

```

        prevIndentDisplayed = currIndent
        showMyDaughter = expanded
        if (db.length > 25) {
            document.write(newOutline)
            newOutline = ""
        }
    }
}

```

First, you call upon two previously defined functions to grab the widget image object and corresponding `onmouseover` message for the statusbar. Two more variables contain the indent property for the item (that is, how many steps indented the item will appear in the outline structure) and the current expanded state, based on the cookie's entry for that item.

Not every entry in the outline database is displayed. For instance, a nested item whose mother is collapsed won't need to be displayed. To find out if an entry should be displayed, the script performs a number of tests on some of its values. An item can be displayed if any of the following conditions are met:

- ♦ The item is a topmost item, with an indentation factor of 0.
- ♦ The item is at the same or smaller indentation level as the previous item displayed.
- ♦ The previous item was tagged as being expanded, and the current item is indented from the previous item by one level.

Over the next few statements, the script pieces together the HTML for the outline entry, starting with the width necessary for the transparent filler image (based on the number of pixels specified for indentations near the top of the script). Next comes the link definition that wraps around the widget image. The following concepts apply to each link:

- ♦ The `HREF` attribute is the `javascript: URL` to invoke the `history.go()` method.
- ♦ The `onmouseover` event handler is set to adjust the status message to the previously retrieved message (notice the `return true` statement to make the setting take effect).
- ♦ The `onclick` event handler is set to call the `toggle()` function, passing the number of the item within the outline database. An `onclick` event handler is carried out before the browser responds to the click of the link by navigating to the URL. Therefore, the `toggle()` function changes the setting of the cookie a fraction of a second before the browser refreshes the document (which relies on that new cookie setting). But click events on widgets that have no children do not need to hit the `toggle()` function. Therefore, the content of the `return` statement is influenced by whether or not the widget image is an endpoint image.

In the next statement, the `newOutline` string accumulation continues with the `` tag specifications for the widget art. Specifying the `HEIGHT` and `WIDTH` attributes for the image is important, partly to help the browser lay out the page more quickly, partly to avoid pesky performance inconsistencies.

Next comes a decision about whether to display the item text as a link or as plain text. The script inspects the `db[i].URL` property to see if it is empty. If so, that means no URL is specified for a link, and the item should be built as plain text.

If a URL is specified for the item, the script instead constructs a link around the text. In this HTML assembly process, numerous calls to properties of the `db` array fetch properties of the entry for the URL, the statusbar message, and the text to display. Notice, too, that the link sets the target of the link to the frame name assigned to `displayTarget` near the top of the script.

As you near the end of the loop, two variable values, `prevIndentDisplayed` and `showMyDaughter`, are updated with settings from the current traversal through the loop. These values influence the display of nested items for the next entry's journey through the loop.

But before looping around again, the script inspects whether the outline is longer than 25 entries. If so, the script writes the outline entries that have accumulated so far, resetting the `newOutline` variable to empty for the next time through the loop. The reasoning behind this last routine is to help long outlines start to display their goods faster. I have seen Web site authors use this outline for literally hundreds of entries. At that quantity, the usually fast JavaScript begins to bog down a bit. By writing lines from a big outline to the page early, the user gets visual feedback that something is happening.

Once outside the loop, the script writes whatever last items may have accumulated in the `newOutline` variable. For outlines with less than 25 items, the whole outline is written in one push; for longer outlines, the value is empty at this point, because the intermediate writings have completed the job.

All that's left is to close up standard tags to finish the document definition:

```
document.write(newOutline)

// end -->
</SCRIPT>
</BODY>
</HTML>
```

Notice that the `document.write()` statement here is not followed by `document.close()`. Because this content is being written as the page loads, the output stream is closed at the end of the page's HTML.

Customization possibilities

Although this DHTML-free outliner is not the fanciest to be found on the Web, it is, nevertheless, quite popular probably due to its ease of customizability and backward compatibility to all but the earliest browsers (you can find the very original version at my Web site). Other page authors have pushed and pulled on this code to tailor it to a variety of special needs.

Alternative displays

At the root of almost all significant customization jobs lie modifications to the `dbRecord` object constructor near the beginning of the page and the HTML assembly portion in the Body. They work hand in hand. For example, one user wants different links in the outline to load pages into different targets. Most links are to load content into another frame of the same frameset, while others are to replace the frameset entirely. In the version provided previously, one target is assumed, and it is set as a global variable. But if you need to provide different targets for each item,

you can add a new property (perhaps named `target`) to the `dbRecord` constructor, and assign the string name of the target (for example, “Frame2”, “_top”) to the property for each item. Then, in the HTML accumulation portion, assign the value of `db[i].target` to that `TARGET` attribute (watching out for the necessary pairings of quote symbols, as shown in other attribute assignments).

Another request asked that the text associated with the plus/minus images be clickable, not to navigate to another page, but to expand and collapse the nested content. All the pieces for this variation are already in place. By performing minor reconstructive surgery on the HTML accumulator script, you can add a branch that looks for the `db[i].mother` property. If it’s `true`, then don’t write the closing `` tag after the widget. Instead, branch to write the `db[i].display` text without its own URL link, and write the widget’s `` tag after the text. Now the widget and text share the same link as the widget originally had.

Cookie-free zones

Not everyone likes to develop with cookies. That’s not a problem for this outliner, even though the previous example uses them liberally. The data that preserves the state of the outline is nothing but a string of 1s and 0s. If you are using a frameset, that string can be preserved as a global variable in the framesetting document.

To minimize the changes needed to the existing code, you can continue to use the same functions — `setCurrState()` and `getCurrState()` — as the interfaces to the reading and writing of the state. Begin by defining a global variable in the Head portion of the framesetting document, initializing it as an empty string:

```
<SCRIPT LANGUAGE="JavaScript">
outlineState = ""
</SCRIPT>
```

Now you can modify the two functions in the outliner page as follows:

```
// ** functions that get and set state data **
// set cookie data
var mycookie = document.cookie
function setCurrState(setting) {
    mycookie = parent.outlineState = setting
}
// retrieve cookie data
function getCurrState() {
    return parent.outlineState
}
```

Notice that there is no need for the label that has to be assigned to a cookie. The variable name keeps this data separate from the rest of the script space.

The only downside to not using a cookie is that the outline state is not preserved if the frameset goes away. If the user revisits the frameset in the same session, the outline state will be reinitialized at its beginning state.

Expanding/collapsing all at once

If you have an extensive outline, you may want to provide a shortcut to the user to expand everything at once or close up the entire outline. Because the string of 1s and 0s maintains the state of the outline, you can use the `db` array to help you

create a new state string, and then apply it to the page. Here are two functions that do the job:

```
function expandAll() {
    expState = ""
    for (i = 1; i < db.length; i++) {
        expState += (db[i].mother) ? "1" : "0"
    }
    setCurrState(expState)
    history.go(0)
}

function collapseAll() {
    collState = ""
    for (i = 1; i < db.length; i++) {
        collState += "0"
    }
    setCurrState(collState)
    history.go(0)
}
```

All you need are a couple of buttons to invoke these functions, and you're in business.

Reducing server access

Through the lifetime of this outliner application, it has seen wildly different behaviors of the various browsers with regard to how much the browser reaches out to the server for each redisplay of the outline. While the `history.go(0)` type of reloading is supposed to be the least onerous, some browsers seem to read the entire file from scratch. This approach is still faster than having a CGI script completely reconfigure a page, but for an extensive outline and a slow Internet connection, the results can be objectionable.

One possible solution is to avoid reloading the page at all. Instead, place all of the code for the outliner management and creation in the framesetting document. Code that currently writes the outline as the page loads can be encapsulated in a function that writes to the frame designated as the outline frame (don't forget the `document.close()` for this writing!). Function calls from the outliner (to `toggle()`, for instance) have to be modified so that the reference is to the function in the parent frame (`parent.toggle(n)`).

Distributing the code around frames may not be as convenient as keeping it all together, but user experience should weigh more heavily than programmer expedience. This practice also opens the possibility for putting all of the outliner code, except for the calls to the constructor functions, in an external `.js` library. You can then put multiple outline contents into multiple `.js` libraries and load the pairs that you need into a frameset.

Using `document.write()` to another frame may still not avoid server access entirely. It is not uncommon for the application of any image file—including those that have been precached—to check the cached version against the modification date of the file on the server. This activity is much faster than downloading the image again, but if you see network activity even after shifting the outliner's scripts

to the frameset, at least you understand what's happening. A version of the application directed from the parent window is contained on the CD-ROM.

Multiple outlines

The example in this chapter assumes that a site will be using only one outline-style table of contents. You can, of course, have multiple outlines for different sections of a Web site or application. But if the outlines all share the same cookie data, then the state of the most recent outline will be applied to the next one that loads. Items will be magically opened. And if the number of items between the two outlines is different, the cookie data can get a bit messy.

To solve this problem, assign a different cookie label for each outline. That prevents one outline's state from stepping on another.

Cascading Style Sheet Version

The advent of Cascading Style Sheets (CSS) brought a number of intriguing possibilities for an application, such as the outliner. Not only can style sheets be used to control the look of the items in the outline, but additional properties make it possible to hide and show elements, including inserting or removing elements from the rendered content. Alas, not all of these features work in NN4, so that the version under discussion in this section resorts to redrawing the outline for NN4. But for IE4+ and W3C DOMs, the response is very fast, and no page reloading is necessary. One of the goals, too, in this application was to reuse as much of the code from earlier versions as possible. Note that this version does not work (or work correctly) with browsers prior to NN4 or IE4.

CSS implementation plan

Many of the compromises in this version resulted from quirky behavior of NN4 with some types of elements and style sheets. I chose to render the outline content as a series of nested DIV elements. If this were being implemented strictly in more well behaved browsers, style sheet control over UL and LI elements would be even more convenient because those elements already have an indentation scheme built into them. With so much HTML code needed to generate the DIV elements and their contents, I decide to trade the cleverness of multidimensional array storage of outline content for the better performance of straight HTML. Each row of content in the outline is set in its own <DIV> block tag set. Any row that had children nested inside contains those items as a nested block.

Style sheets afforded the design a handy behavior. Hiding and showing blocks via the CSS-Positioning `visibility` property (see Chapter 30) is not an apt solution here, because hiding an item does not remove it from the page rendering. Therefore, unless the page included a ton of positioning code to overlap hidden items with visible items (which would have worked in NN4, but at the price of substantial increases in code and inflexibility), the outline would not cinch up if a branch is collapsed. To the rescue comes the `display` property of a style. One value of this property (`none`) not only hides the block, but it temporarily removes it from the rendering order of the page. Any items rendered below it that are visible (that is, whose `display` property is set to `block`) scoot up to render after the previous visible item.

Setting the `display` property has slightly different results in NN4 and more modern DOMs. In NN4, you can set the property after the block has been rendered on

the page, but its appearance does not change; in both the IE4+ and W3C DOMs, the change is immediate, with the rest of the page reflowing to adjust to the change in the block's visibility and presence. Therefore, for NN4, the page still needs to reload itself and remember the state of the outline between reloads (via the same cookie mechanism used for the earlier version) so that the page can set the property value as the page loads. And except for only a couple of places in the code, both the IE4+ and W3C DOMs share positioning code.

The CSS version uses the same cookie value (a sequence of 1 and 0 values) to represent the visible or hidden state of each item as in the old version. To convey the change of state, however, the function called by the click of an icon widget must pass the index values of the child items affected by the expansion or collapse of a node. This means that more of the HTML—in this case, the parameters of the functions—has to be hard-wired to the structure of the outline, as you see shortly. Less of this would be necessary if NN4's implementation of CSS offered the same level of scriptable introspection into HTML elements as IE4's implementation: We'd be able to employ the style property inheritance behavior to simplify the way blocks are shown and hidden. Because the two classes of browsers supported in this example are so different in this regard, the scripting reflects the lowest common denominator for controlling the toggle of expanded and collapsed states.

The CSS code

By putting so much of the content directly into HTML, the scripting component of the CSS outliner version is significantly smaller than the older version. Where possible, I stayed with the same function and variable naming schemes of the previous version.

At the top of the document, I define three styles for the amount of indentation required by the three indentation levels of my sample outline. If the outline were to go to more levels, I would add styles accordingly.

```
<HTML>
<HEAD>
<STYLE TYPE="text/css">
  DIV.indent0 {margin-left:0}
  DIV.indent1 {margin-left:10}
  DIV.indent2 {margin-left:20}
</STYLE>
```

Scripting begins by setting some global variables. Browser-specific branching comes into play later, but in an effort to stamp out explicit version detection, the code here relies on object detection to set the requisite flags. Only browsers capable of the CSS style scripting needed here have a `document.styleSheets` property, so flags are set for the two supported browser classes. These flags are set here primarily as a convenience for writing branching code later. Rather than constantly retesting for the presence of the property, the global flags are shorter and marginally faster. Two more variables hold their respective browser class state values, with the NN4 version maintaining a copy of the cookie as a variable for performance reasons.

```
<SCRIPT LANGUAGE="JavaScript">
// global variables
var isNN4, isCSS, CSScurrState, NN4Cookie = document.cookie
```

```

if (document.styleSheets) {
    isCSS = true
    isNN4 = false
} else {
    isCSS = false
    isNN4 = true
}

```

To each of the cookie storage functions from the original version, I add a branch to handle the storage and retrieval of state data for CSS browsers, simply setting and getting the global variable. This may seem to be more indirect than is necessary, but it is essential to allow the reuse of many functions in other parts of the code so that those areas don't have to worry about browser platform. Notice that the label for this outline's cookie is slightly different from that of the earlier version. This difference allows you to open both outliners with NN4 in the same session and not worry about one cookie value overlapping with the other.

```

// ** functions that get and set persistent data **
// set persistent data
function setCurrState(setting) {
    if (isNN4) {
        NN4Cookie = document.cookie = "currState2=" + escape(setting)
    } else {
        // for CSS, data is saved as a global variable instead of cookie
        CSScurrState = setting
    }
}

// retrieve persistent data
function getCurrState() {
    if (isCSS) {
        // for CSS, data is in global var instead of cookie
        return CSScurrState
    }
    var label = "currState2="
    var labelLen = label.length
    var cLen = NN4Cookie.length
    var i = 0
    while (i < cLen) {
        var j = i + labelLen
        if (NN4Cookie.substring(i,j) == label) {
            var cEnd = NN4Cookie.indexOf(";",j)
            if (cEnd == -1) {
                cEnd = NN4Cookie.length
            }
            return unescape(NN4Cookie.substring(j,cEnd))
        }
        i++
    }
    return ""
}

```

The `toggle()` function is called by the `onClick` event handler of the links surrounding the widget icon art in the outline. A variable number of parameters are passed to this function, so that the parameters are extracted and analyzed via the `arguments` property of the function. Both browsers with only a few small

browser-specific branches use a great deal of the code. Inside the large for loop, a CSS branch dynamically changes the setting of the `style.display` property. For NN4, the page is reloaded after all changes to the cookie version of the state are saved. After the NN4 version goes off to reload the page, the CSS version swaps the image of the toggled widget. As a final touch, the window is given focus so that IE/Windows browsers lose the dotted rectangle around the clicked image.

```
// **function that updates persistent storage of state**
// toggles an outline mother entry, storing new value
function toggle() {
    var newString = ""
    var expanded, n
    // get all <DIV> tag objects in IE4/W3C DOMs
    if (document.all) {
        var allDivs = document.all.tags("DIV")
    } else if (document.getElementsByTagName) {
        var allDivs = document.getElementsByTagName("DIV")
    }
    var currState = getCurrState() // of whole outline
    // assemble new state string based on passed parameters
    for (var i = 0; i < arguments.length; i++) {
        n = arguments[i]
        expanded = currState.charAt(n) // of clicked item
        newString += currState.substring(0,n)
        newString += expanded ^ 1 // Bitwise XOR clicked item
        newString += currState.substring(n+1,currState.length)
        currState = newString
        newString = ""
        if (isCSS) {
            // dynamically change display style without reloading
            if (expanded == "0") {
                allDivs[n].style.display = "block"
            } else {
                allDivs[n].style.display = "none"
            }
        }
    }
    setCurrState(currState) // write new state back to cookie
    if (isNN4) {
        location.reload()
    }
    // swap images in CSS versions
    var img = document.images["widget" + (arguments[0]-1)]
    img.src = (img.src.indexOf("plus.gif") != -1) ?
        "minus.gif" : "plus.gif"
    window.focus()
}
```

A prerequisite for loading the page to begin with is setting the initial value of the state. This is the only part of the script that must be hard-wired based on the structure of the outline—string assigned to `initState` will be different with each outline. The goal here is to set each block assigned to the `indent0` style class to 1

while all others are set to 0. These settings allow the first display of the outline to show all the root nodes, with all other items collapsed.

```
// initialize 'current state' storage field
if (!getCurrState()) {
    // must be hard-wired to outline structure with "1" for
    // each indent0 class item, "0" for all others
    initState = "1000010000"
    setCurrState(initState)
}
```

With the initial outline state saved in the above code, the following statements execute at load time to write a <STYLE> tag set for NN4. This tag sets the display property of all collapsed blocks to none. As you see in the HTML coming up, blocks are assigned ID attributes with the letter “a” followed by a sequence number starting with zero.

```
// for Navigator 4, set display style for flagged IDs to 'none'
// each time the page (re)loads
if (isNN4) {
    document.write("<STYLE TYPE='text/css'>")
    var visState = getCurrState()
    for (var i = 0; i < visState.length; i++) {
        if (visState.charAt(i) == "0") {
            document.write("#a" + i + " {display:none}\n")
        }
    }
    document.write("</STYLE>")
}
```

Initial settings of the display property for IE4+ can be done programmatically only after the document loads (the tags must exist before their properties can be adjusted). The following init() function is called from the onLoad event handler. Each browser class has a different set of initialization tasks. Both branches rely on the current state setting, so that value is retrieved just once. In the CSS branch, the style.display properties for hidden blocks are set to none. For NN4, on the other hand, the style.display properties are set as the page reloads, but this loop swaps the widget image for expanded blocks to the minus.gif version.

```
// for CSS, initialize flagged tags to style display = "none"
// for NN4, set affected images to minus.gif
function init() {
    var visState = getCurrState()
    if (isCSS) {
        for (var i = 0; i < visState.length; i++) {
            if (visState.charAt(i) == "0") {
                // branch for browser object capability
                if (document.all) {
                    document.all("a" + i).style.display = "none"
                } else if (document.getElementsByTagName) {
                    document.getElementById("a" + i).style.display = "none"
                }
            }
        }
    }
    } else if (isNN4) {
        for (i = 0; i < visState.length; i++) {
```

```

        if (visState.charAt(i) == "1") {
            if (i+1 < visState.length && visState.charAt(i+1) == "1") {
                if (document.images["widget" + i]) {
                    document.images["widget" + i].src = "minus.gif"
                }
            }
        }
    }
}
</SCRIPT>
</HEAD>

```

```

<BODY onLoad="init()">
<CENTER><H3>Composition of Selected Foods</H3><HR></CENTER>

```

Now begins the HTML that defines the content of the outline. For readability, I have formatted the `<DIV>` tag sets to follow the indentation of the outline data (this listing looks much better if you open the file from the CD-ROM in your text editor with word wrap turned off). Each tag includes a `CLASS` attribute pointing to a class defined in the first `<STYLE>` tag of the page. Each tag also includes an `ID` attribute whose name begins with the letter “a” and a sequential serial number, starting with zero. Navigator uses the `ID` attributes to help it assign `display` property settings during each reload.

Like the older version of the outliner, each entry includes an image (surrounded by a clickable link) and a text entry (which may or may not be a link to a document). The link around the image includes a `javascript: URL` for the `HREF` attribute. When a link is for a widget that is a mother item, the parameters to the `toggle()` function are the serial numbers of the immediate children `IDs` whose `display` properties are to be adjusted in the `toggle()` function. These passed items only need to be in the immediate children, because any of their children inherit the `display` property of their parents. For example, the first widget toggles items 1 and 2 (`ids a1` and `a2`). Item 2 happens to be a parent to items 3 and 4. But when the `display` property of item 2 is set to `none`, then none of its children (items 3 and 4) are displayed, no matter how their `display` properties are set.

`IMG` elements associated with each toggled `DIV` are named along similar lines, with the name starting with “widget” and the same serial number as the containing `DIV`. If you look at the end of the `toggle()` function again, you’ll see that the name for the `IMG` element is derived from the first parameter received by the `toggle()` function. That first parameter will always be one number higher than the serial number for the widget image to swap. To help you visualize the numbering scheme used within the example, the numbered identifiers and methods that relay associated numbers are shown in boldface.

```

<DIV CLASS=indent0 ID="a0">

```

The CSS version (for the identical outline content) is a slightly smaller file size than the older, compatible one, but not so big a difference as to influence your choice. Browser compatibility should be your number one criterion. Ease of modification for changing content and improved user experience for browsers following the CSS branch are tied in second.

A Futuristic (XML) Outline

As XML and its associated technologies head toward a solid standardized footing, the latest browsers available as this edition is being written provide mixed support for some of the key features of an ideal environment. As those issues are sorting themselves out, getting to know portions of XML through the IE5+/Windows XML data island features is possible. While it's not normally okay to embed XML in an HTML document (that is, the two designations specify unique document types), IE5+/Windows provides an `<XML>` tag, in which you can insert XML tags. Scripts can access the elements inside the XML data island, referencing those elements as child nodes of the XML element. See Chapter 33 for the reference material on the IE XML element.

Birth of an XML specification

Collapsible outlines provide convenient ways to organize hierarchical information all around us. You'd be hard-pressed to find a more active proponent of the outline than Dave Winer, CEO of UserLand Software, Inc. (<http://www.userland.com>). Dave is a veteran software developer, as well as author and outspoken Web publisher. His www.scripting.com Web site is a popular destination if you want to find out the latest Internet and computing technology "buzz."

As an outgrowth of development for his company's Web tools, Dave looked to the XML structure to assist in representing outline content in a shareable, easily parseable format. The result is a specification called Outline Processor Markup Language, or OPML for short. You can read all about the formal specification at <http://www.opml.org/spec>. Like virtually all XML, OPML is intended to be

written by software, not humans (although humans input the data via a user-friendly front-end provided by the software). Even so, the format of an OPML outline is extremely readable by humans, and, with little more trouble than writing basic HTML tags manually, you can represent an outline in this format yourself.

A plain OPML file, saved as an `.xml` file, can be viewed through the native XML parsers of IE5+ and NN6. These parsers automatically render XML tags in the same hierarchical fashion as OPML encourages outlines to be structured. But such rendering is under strict control of the browser, unless you also get involved with XML style sheets (the XSL and XSLT standards), at which point, browser implementation incompatibilities can make the going tough.

I liked the OPML data format when I first saw it, and I think it's a convenient way to convey an outline's data to the client, at which point JavaScript and the browser's DOM can take over to provide interesting visuals for the content and interaction with the content. Thus was born the last example of this chapter, in which the outliner's data is delivered not in the form of scripted arrays or hard-wired HTML DIV elements. Instead, the data arrives in its native XML (OPML) format inside an IE5+/Windows XML data island. Rendering of the native XML is suppressed, and scripts take over to do the rest.

OPML outliner prep

The appearance of widgets and text for the new outliner has changed to more closely emulate the kinds of outline presentations that you see in some Windows programs (see Figure 52-2). For demonstration purposes, the same frameset structure and outline content from earlier examples are used for the OPML version so that you can more easily see the differences in implementations and grasp new concepts presented here. For example, the comparison of how the outline data is delivered in the form of JavaScript objects (the first example) and OPML is enlightening.

As you recall, a custom object constructor function generated one JavaScript object for each outline entry. The properties of the object are completely under your control, so that you can add properties (such as the target of an entry's link), whose values influence the way the entry is rendered and the way it behaves. OPML has a similar extensibility feature. Each outline entry is nothing more than a tag. An entry that does not have any nested child nodes can use the XML shortcut of combining a start and end tag inside one set of angle brackets:

```
<tagName attribute="value" ... />
```

And any entry that has nested nodes contains the nested nodes between its start and end tags, as shown here with the actual tag names used in OPML (indentation is optional, but increases readability):

```
<outline text="text">
  <outline text="text"/>
  <outline text="text"/>
</outline
```

Figure 52-2: OPML-based outliner style

If you want to associate more information about an entry, simply add an attribute. For example, if an entry is to behave as a link, you can convey that information with an attribute whose name you determine. When it comes time for your scripts to render the content in HTML, the scripts access the attribute values and generate the associated HTML for the attributes (you see an example of this in the code).

The true beauty of the OPML structure (and XML in general) is that the parent-child relationships are automatically implied by the element containment. Unlike the JavaScript custom object in the first example, the author does not have to specify how many levels deep an entry is, or whether it has any child nodes: The XML containment hierarchy describes all of that information. Suddenly, all of the W3C DOM gobbledygook about nodes, child nodes, and attributes become your friend, as your scripts convert the element hierarchy into a renderable hierarchy of your design.

The XML and HTML code

Because our focus is so tight on the outliner content, you can start the exploration of the outliner code from the HTML BODY element downward, where the outline data is embedded in an IE5+/Windows XML element.

```
<BODY onLoad="init('outlineXML')">
<XML ID="outlineXML">
<opml version="1.0">
  <head>
    <title>A Modern Outline</title>
    <dateCreated>Thu, 16 Nov 2000 02:40:00 GMT</dateCreated>
    <dateModified>Fri, 22 Dec 2000 19:35:00 GMT</dateModified>
    <ownerName>Danny Goodman</ownerName>
    <ownerEmail>dannyg@dannyg.com</ownerEmail>
    <expansionState></expansionState>
    <vertScrollState>1</vertScrollState>
    <windowTop></windowTop>
    <windowLeft></windowLeft>
    <windowBottom></windowBottom>
    <windowRight></windowRight>
  </head>
  <body>
    <outline text="Peas">
      <outline text="Boiled" uri="foods.htm#boiled"/>
      <outline text="Canned" uri="foods.htm#canned">
        <outline text="Alaska" uri="foods.htm#alaska"/>
        <outline text="Low-Sodium" uri="foods.htm#losodium"/>
      </outline>
    </outline>
    <outline text="Pickles">
      <outline text="Cucumber" uri="foods.htm#cucumber">
        <outline text="Dill" uri="foods.htm#dill"/>
        <outline text="Fresh" uri="foods.htm#fresh"/>
        <outline text="Sour" uri="foods.htm#sour"/>
      </outline>
    </outline>
  </body>
</opml>
</XML>

<DIV ID="content"></DIV>
</BODY>
</HTML>
```

Everything inside the XML element is textbook OPML version 1.0 form. Notice that the OPML syntax reuses element names that are found in all HTML files (for example, head, title, body). The XML island behavior isolates these tags from the browser's HTML rendering engine, so the browser won't confuse the two "documents." The only other HTML delivered in the document is an empty DIV element, which is used as the container for the outline HTML that the scripts generate as a result of the `onLoad` event handler's invocation of the `init()` function.

Also, go back to the top of the document to see the style sheets, which have an important place in delivering an XML island:

```
<HTML>
<HEAD>
<STYLE TYPE="text/css">
  XML {display:none}
  .row {vertical-align:middle; font-size:12px; font-family:Arial,sans-serif}
  .OLBlock {display:none}
  IMG {vertical-align:text-top}
</STYLE>
```

To prevent the XML block from rendering on the page, the `display` style property is set to `none` for the XML tag selector. This keeps the page clear for insertion of script-generated HTML. The other style sheet rules apply to content created by the scripts.

Setting the scripted stage

All scripts for this page are in the HEAD (although they could also be linked in from an external `.js` file). First on the docket is establishing several global variables that get used a lot within the rest of the code and make it easy to customize important visible properties, especially widget art. Due to the art choices made for this version, there are separate versions for items that appear as first, middle, and end items for different nesting states.

```
<SCRIPT LANGUAGE="JavaScript">
// global variables
// art files and sizes for widget styles and spacers
// (all images must have same height/width)
var collapsedWidget = "oplus.gif"
var collapsedWidgetStart = "oplusStart.gif"
var collapsedWidgetEnd = "oplusEnd.gif"
var expandedWidget = "ominus.gif"
var expandedWidgetStart = "ominusStart.gif"
var expandedWidgetEnd = "ominusEnd.gif"
var nodeWidget = "onode.gif"
var nodeWidgetEnd = "onodeEnd.gif"
var emptySpace = "oempty.gif"
var chainSpace = "ochain.gif"
var widgetWidth = "20"
var widgetHeight = "16"
var currState = ""
var displayTarget = "Frame2"
```

The `init()` function, invoked by the `onLoad` event handler, starts the content creation in motion. The basic sequence is to first make sure that the browser is capable of recognizing an XML data island. If the validation is okay, then a reference to the BODY portion of the outline data is retrieved so that many other functions are able to dive into the outliner hierarchy. Notice that elements of the XML data island are disguised from view of the document object's normal scope. Access must be made by way of the XML object, which then exposes its elements. The reference to the OPML BODY element is passed to the `makeHTML()` function, which returns

the entire outline HTML to be assigned to the `innerHTML` property of the empty DIV element delivered with the document.

```
// initialize first time
function init(outlineID) {
    if (supportVerified(outlineID)) {
        // demo how to get outline head elements
        var hdr =
document.getElementById(outlineID).getElementsByTagName("head")[0]
        // get outline body elements for iterative conversion to HTML
        var ol =
document.getElementById(outlineID).getElementsByTagName("body")[0]
        // wrap whole outline HTML in a span
        var olHTML = "<SPAN ID='renderedOL'>" +
            makeHTML(outlineID, ol) + "</SPAN>"
        // throw HTML into 'content' DIV for display
        document.getElementById("content").innerHTML = olHTML
        initExpand(outlineID)
    }
}
```

Validation of browser support is handled by the `supportVerified()` function. This function is in search of the `XMLDocument` property of the XML element object. The property's presence indicates that the browser has what it takes to treat embedded XML as a data island. Incremental tests are needed so that earlier browsers don't choke on the reference to the property.

```
// verify that browser supports XML islands
function supportVerified(testID) {
    if (document.getElementById &&
document.getElementById(testID) &&
document.getElementById(testID).XMLDocument) {
        return true
    } else {
        var reply = confirm("This example requires a browser with XML data
island support, such as IE5+/Windows. Go back to previous page?")
        if (reply) {
            history.back()
        } else {
            return false
        }
    }
    return false
}
```

Accumulating the HTML

From the `init()` function, a call to the `makeHTML()` function starts the most complex actions of the scripts on this page. This function walks the node hierarchy of the outline's BODY elements, deciphering which ones are containers and which ones are end points.

Two global variables are used to keep track of how far the node walk progresses because this function calls itself from time to time to handle nested branches of the node tree. Because a reflexive call to a function starts out with new values for local variables, the globals operate as pointers to let statements in the function know which node is being accessed. The numbers get applied to an ID attribute assigned to the DIV elements holding the content.

One of the fine points of the design of this outline is the way space to the left of each entry is assembled. Unlike the earlier outlines in this chapter, this one displays vertical dotted lines connecting nodes at the same level. There isn't a vertical line for every clickable node appearing above the item, because a clickable node may have no additional siblings, meaning that the space is blank. To see what I mean, open the OPML example, and expand the Peas and Canned nodes (or see Figure 52-2). The Canned node is the end of the second "column," so the space beneath the icon is blank. That's what some of the code in `makeHTML()` named "prefix" is dealing with: Accumulating just the right combination of dotted line (`chain.gif`) and blank (`empty.gif`) images in sequence before the outline entry.

Another frequent construction throughout this function is a three-level conditional expression. This construction is used to determine whether the image just to the left of the item's text should be a start, middle, or end version of the image. The differences among them are subtle (having to do with how the vertical dotted line extends above or below the widgets). All of these decisions are made from information revealed by the inherent structure of the OPML element nesting. The listing in the book looks longer than it truly is because so many long or deeply nested lines must be wrapped to the next line. Viewing the actual file in your text editor should calm your fears a bit.

```
// counters for reflexive calls to makeHTML()
var currID = 0
var blockID = 0
// generate HTML for outline
function makeHTML(outlineID, ol, prefix) {
    var output = ""
    var nestCount, link, nestPrefix
    prefix = (prefix) ? prefix : ""
    for (var i = 0; i < ol.childNodes.length ; i++) {
        nestCount = ol.childNodes[i].childNodes.length
        output += "<DIV CLASS='row' ID='line" + currID++ + "'>\n"
        if (nestCount > 0) {
            // for entries that are also parents
            output += prefix
            output += "<IMG ID='widget" + (currID-1) +
                "' SRC='" + ((i== ol.childNodes.length-1) ?
                    collapsedWidgetEnd : (blockID==0) ?
                    collapsedWidgetStart : collapsedWidget)
            output += "' HEIGHT=" + widgetHeight + " WIDTH=" +
                widgetWidth
            output += " TITLE='Click to expand/collapse nested items.'
                onClick='toggle(this," + blockID + ")'>"
            // if a uri is specified, wrap the text inside a link
            link = (ol.childNodes[i].getAttribute("uri")) ?
                ol.childNodes[i].getAttribute("uri") : ""
            if (link) {
                output += "&nbsp;<A HREF='" + link +
                    "' CLASS='itemTitle' TITLE='" + link +
                    "' TARGET='" + displayTarget + "'>"
            } else {
                output += "&nbsp;<A CLASS='itemTitle' TITLE='" +
                    link + "'>"
            }
        }
        // finally! the actual text of the entry
```

```

        output += "&nbsp;" + ol.childNodes[i].getAttribute("text") +
            "</A>"
        currState += calcBlockState(outlineID, currID-1)
        output += "<SPAN CLASS='OLBlock' BLOCKNUM='" + blockID +
            "' ID='OLBlock" + blockID++ + "'>"
        // accumulate prefix art for next indented level
        nestPrefix = prefix
        nestPrefix += (i == ol.childNodes.length - 1) ?
            "<IMG SRC='" + emptySpace + "' HEIGHT=16 WIDTH=20>" :
            "<IMG SRC='" + chainSpace + "' HEIGHT=16 WIDTH=20>"
        // reflexive call to makeHTML() for nested elements
        output += makeHTML(outlineID, ol.childNodes[i], nestPrefix)
        output += "</SPAN></DIV>\n"
    } else {
        // for endpoint nodes
        output += prefix
        output += "<IMG ID='widget" + (currID-1) + "' SRC='" +
            ((i == ol.childNodes.length - 1) ?
                nodeWidgetEnd : nodeWidget)
        output += "' HEIGHT=" + widgetHeight + " WIDTH=" +
            widgetWidth + ">"
        // check for links for these entries
        link = (ol.childNodes[i].getAttribute("uri")) ?
            ol.childNodes[i].getAttribute("uri") : ""
        if (link) {
            output += "&nbsp;<A HREF='" + link +
                "' CLASS='itemTitle' TITLE='" +
                link + "' TARGET='" + displayTarget + "'>"
        } else {
            output += "&nbsp;<A CLASS='itemTitle' TITLE='" +
                link + "'>"
        }
        // grab the text for these entries
        output += ol.childNodes[i].getAttribute("text") + "</A>"
        output += "</DIV>\n"
    }
}
return output
}

```

As with the HTML assembly code of the first outliner, if you were to add attributes to OUTLINE elements in an OPML outline (for example, a URL for an icon to display in front of the text), it is in `makeHTML()` that the values would be read and applied to the HTML being created.

The only other function invoked by the `makeHTML()` function is `calcBlockState()`. This function looks into one of the OPML outline's HEAD elements, called EXPANSIONSTATE. This element's values can be set to a comma-delimited list of numbers corresponding to nodes that are to be shown expanded when the outline is first displayed. The `calcBlockState()` function is invoked for each parent element. The element's location is compared against values in the EXPANSIONSTATE element, if there are any, and returns the appropriate 1 or 0 value for the state string being assembled for the rendered outline.

```

// apply default expansion state from outline's header
// info to the expanded state for one element to help
// initialize currState variable
function calcBlockState(outlineID, n) {
    var ol = document.getElementById(outlineID).getElementsByName("body")[0]
    var outlineLen = ol.getElementsByTagName("outline").length
    // get OPML expansionState data
    var expandElem =
document.getElementById(outlineID).getElementsByName("expansionState")[0]
    var expandedData = (expandElem.childNodes.length) ?
        expandElem.firstChild.nodeValue.split(",") : null
    if (expandedData) {
        for (var j = 0; j < expandedData.length; j++) {
            if (n == expandedData[j] - 1) {
                return "1"
            }
        }
    }
    return "0"
}

```

The final act of the initialization process is a call to the `initExpand()` function. This function loops through the `currState` global variable (whose value was written in `makeHTML()` with the help of `calcBlockState()`) and sets the `display` property to `block` for any element designed to be expanded at the outset. HTML element construction in `makeHTML()` is performed in such a way that each parent DIV has a SPAN nested directly inside of it; and inside that SPAN are all the child nodes. The `display` property of the SPAN determines whether all of those children are seen or not.

```

// expand items set in expansionState XML tag, if any
function initExpand(outlineID) {
    for (var i = 0; i < currState.length; i++) {
        if (currState.charAt(i) == 1) {
            document.getElementById("OLBlock" + i).style.display = "block"
        }
    }
}

```

By the time the `initExpand()` function has run — a lot of setup code that executes pretty quickly — the rendered outline is in a steady state. Users can now expand or collapse portions by clicking the widget icons.

Toggling node expansion

All of the widget images in the outline have `onClick` event handlers assigned to them. The handlers invoke the `toggle()` function, passing parameters consisting of a reference to the `IMG` element object receiving the event and the serial number of the SPAN block nested just inside the DIV that holds the image. With these two pieces of information, the `toggle()` function sets in motion the act of inverting the expanded/collapsed state of the element and the plus or minus version of the icon image. The `blockNum` parameter corresponds to the position within the `currState` string of 1s and 0s holding the flag for the expanded state of the block. With the current value retrieved from `currState`, the value is inverted through

swapState(). Then, based on the new setting, the display property of the block is set accordingly, and widget art is changed through two special-purpose functions.

```
// toggle an outline mother entry, storing new state value;
// invoked by onClick event handlers of widget image elements
function toggle(img, blockNum) {
    var newString = ""
    var expanded, n
    // modify state string based on parameters passed IMG
    expanded = currState.charAt(blockNum)
    currState = swapState(currState, expanded, blockNum)
    // dynamically change display style
    if (expanded == "0") {
        document.getElementById("OLBlock" + blockNum).style.display =
            "block"
        img.src = getExpandedWidgetState(img.src)
    } else {
        document.getElementById("OLBlock" + blockNum).style.display =
            "none"
        img.src = getCollapsedWidgetState(img.src)
    }
}
```

Swapping the state of the currState variable utilizes the same XOR operator employed by the first outliner in this chapter. The entire currState string is passed as a parameter. The indicated digit is segregated and inverted, and the string is reassembled before being returned to the calling statement in toggle().

```
// invert state
function swapState(currState, currVal, n) {
    var newState = currState.substring(0,n)
    newState += currVal ^ 1 // Bitwise XOR item n
    newState += currState.substring(n+1,currState.length)
    return newState
}
```

As mentioned earlier, each of the clickable widget icons (plus and minus) can be one of three states, depending on whether the widget is at the start, middle, or end of a vertical-dotted chain. The two image swapping functions find out (by inspecting the URLs of the images currently occupying the IMG element) which version is currently in place so that, for instance, a starting plus (collapsed) widget is replaced with a starting minus (expanded) widget. This is a case of going the extra mile for the sake of an improved user interface.

```
// retrieve matching version of 'minus' images
function getExpandedWidgetState(imgURL) {
    if (imgURL.indexOf("Start") != -1) {
        return expandedWidgetStart
    }
    if (imgURL.indexOf("End") != -1) {
        return expandedWidgetEnd
    }
    return expandedWidget
}
```

```
// retrieve matching version of 'plus' images
function getCollapsedWidgetState(imgURL) {
    if (imgURL.indexOf("Start") != -1) {
        return collapsedWidgetStart
    }
    if (imgURL.indexOf("End") != -1) {
        return collapsedWidgetEnd
    }
    return collapsedWidget
}
```

Wrap up

There's no question that the amount and complexity of the code involved for the OPML version of the outliner are significant. The "pain" associated with developing an application such as this is all up front. After that, the outline content is easily modifiable in the OPML format (or perhaps by some future editor that produces OPML output).

Even if you don't plan to implement an OPML outline, the explanation of how this example works should drive home the importance of designing data structures that assist not only the visual design but also the scripting that you use to manipulate the visual design.

Further Thoughts

The advent of CSS and element positioning has prompted numerous JavaScripters to develop another kind of hierarchical system of pop-up or drop-down menus. You can find examples of this interface at many of the JavaScript source Web sites listed in Appendix D. Making these kinds of menus work well in NN4, IE4+, and W3C DOMs is a lot of hard work, and if you can adopt code already ironed out by others, then all the better.

Most of the code you find, however, will require a fair amount of tweaking to blend the functionality into the visual design that you have or are planning for your Web site. Finding two implementations on the Web that look or behave the same way is rare. As long as you're aware of what you'll be getting yourself into, you are encouraged to check out these interface elements. By hiding menu choices except when needed, valuable screen real estate is preserved for more important, static content.

Application: Calculations and Graphics

When the scripting world had its first pre-release peeks at JavaScript (while Netscape was still calling the language LiveScript), the notion of creating interactive HTML-based calculators captured the imaginations of many page authors. Somewhere on the World Wide Web, you can find probably every kind of special-purpose calculation normally done by scientific calculators and personal computer programs — leaving only weather-modeling calculations to the supercomputers of the world.

In the search for my calculator gift to the JavaScript universe, I looked around for something more graphical. Numbers, by themselves, are pretty boring; so any way the math could be enlivened was fine by me. Having been an electronics hobbyist since I was a kid, I recalled the color-coding of electronic resistor components. The values of these gizmos aren't printed in plain numbers anywhere. You have to know the code and the meaning of the location of the colored bands to arrive at the value of each one. I thought that this calculator would be fun to play with, even if you don't know what a resistor is.

The Calculation

To give you an appreciation for the calculation that goes into determining a resistor's value, here is the way the system works. Three closely spaced color bands determine the resistance value in ohms. The first (leftmost) band is the tens digit; the second (middle) band is the ones digit. Each color has a number from 0 through 9 assigned to it (black = 0, brown = 1,

53

CHAPTER

In This Chapter

Precached images

Math calculations

CGI-like image
assembly

and so on). Therefore, if the first band is brown and the second band is black, the number you start off with is 10. The third band is a multiplier. Each color determines the power of ten by which you multiply the first digits. For example, the red color corresponds to a multiplier of 102, so that 10×102 equals 1,000 ohms.

A fourth band, if present, indicates the tolerance of the component — how far, plus or minus, the resistance measurement can fluctuate due to variations in the manufacturing process. Gold means a tolerance of plus-or-minus 5 percent; silver means plus-or-minus 10 percent; and no band means a 20 percent tolerance. A pinch of extra space typically appears between the main group of three-color bands and the one tolerance band.

User Interface Ideas

The quick-and-dirty, non-graphical approach for a user interface was to use a single frame with four SELECT elements defined as pop-up menus (one for each of the four color bands on a resistor), a button to trigger calculation, and a field to show the numeric results.

How dull.

It occurred to me that if I design the art carefully, I can have JavaScript assemble an updated image of the resistor consisting of different slices of art: static images for the resistor's left and right ends, and variable slivers of color bands for the middle. Rather than use the brute force method of creating an image for every possible combination of colors (3,600 images total!), a far more efficient approach is to have one image file for each color (12 colors plus 1 empty) and enable JavaScript to call them from the server, as needed, in the proper order. If not for client-side JavaScript, a CGI script on the server would have to handle this kind of intelligence and user interaction. But with this system, any dumb server can dish up the image files as called by the JavaScript script.

The first generation of this resistor calculator used two frames, primarily because I needed a second frame to update the calculator's art dynamically while keeping the pop-up color menus stationary. Images couldn't be swapped back in those frontier days, so the lower frame had to be redrawn for each color choice. Fortunately, NN3 and IE4 enabled me to update individual image objects in a loaded document without any document reloading. Moreover, with all the images pre-cached in memory, page users experience no (or virtually no) delay in making a change from one value to another.

The design for the new version is a simple, single-document interface (see Figure 53-1). Four pop-up menus let you match colors of a resistor, whereas the `onChange` event handler in each menu automatically triggers an image and calculation update. To hold the art together on the page, a table border surrounds the images on the page, whereas the numeric value of the component appears in a text field.

Figure 53-1: The Resistor Calculator with images inside a table border

The Code

All the action takes place in the file named `resistor.htm`. A second document is an introductory HTML text document that explains what a resistor is and why you need a calculator to determine a component's value. The article, called *The Path of Least Resistance*, can be viewed in a secondary window from a link in the main window. Here you will be looking only at `resistor.htm`, which has been updated to include style sheets.

The document begins in the traditional way. It specifies a JavaScript 1.1-level language because you will be using several features of that language version:

```
<HTML>
<HEAD>
<TITLE>Graphical Resistance Calculator</TITLE>
<STYLE TYPE="text/css">
BODY {font-family:Arial, Helvetica, serif}
</STYLE>
<SCRIPT LANGUAGE="JavaScript1.1">
<!-- hide script from nonscriptable browsers
```

Basic arrays

In calculating the resistance, the script needs to know the multiplier value for each color. If not for the last two multiplier values actually being negative multipliers (for example, 10^{-1} and 10^{-2}), I could have used the index values without having to create this array. But the two out-of-sequence values at the end make it easier to work with an array rather than to try special-casing these instances in later calculations:

```
// create array listing all the multiplier values
var multiplier = new Array()
multiplier[0] = 0
multiplier[1] = 1
multiplier[2] = 2
multiplier[3] = 3
multiplier[4] = 4
multiplier[5] = 5
multiplier[6] = 6
multiplier[7] = 7
multiplier[8] = 8
multiplier[9] = 9
multiplier[10] = -1
multiplier[11] = -2
// create object listing all tolerance values
var tolerance = new Array()
tolerance[0] = "+/-5%"
tolerance[1] = "+/-10%"
tolerance[2] = "+/-20%"
```

Although the script doesn't do any calculations with the tolerance percentages, it needs to have the strings corresponding to each color for display in the pop-up menu. The `tolerance` array is there for that purpose.

Calculations and formatting

Before the script displays the resistance value, it needs to format the numbers in values that are meaningful to those who know about these values. Just as measures of computer storage bytes, high quantities of ohms are preceded with “kilo” and “meg” prefixes, commonly abbreviated with the “K” and “M” letters. The `format()` function determines the order of magnitude of the final calculation (from another function shown in the following section) and formats the results with the proper unit of measure:

```
// format large values into kilo and meg
function format(ohmage) {
    if (ohmage >= 1e6) {
        ohmage /= 1e6
        return "" + ohmage + " Mohms"
    } else {
        if (ohmage >= 1e3) {
            ohmage /= 1e3
            return "" + ohmage + " Kohms"
        }
    }
}
```

```

        } else {
            return "" + ohmage + " ohms"
        }
    }
}

```

The selections from the pop-up menus meet the calculation formulas of resistors in the `calcOhms()` function. Because this function is triggered indirectly by each of the `SELECT` objects, sending any of their parameters to the function is a waste of effort. Moreover, the `calcOhms()` function is invoked by the `onLoad` event handler, which is not tied to the form or its controls. Therefore, the function obtains the reference to the form and then extracts the necessary values of the four `SELECT` objects by using explicit (named) references. Each value is stored in a local variable for convenience in completing the ensuing calculation.

Recalling the rules used to calculate values of the resistor bands, the first statement of the calculation multiplies the “tens” pop-up value times 10 to determine the tens digit and then adds the ones digit. From there, the combined value is multiplied by the exponent value of the selected multiplier value. Notice that the expression first assembles the value as a string to concatenate the exponent factor and then evaluates it to a number. Although I try to avoid the `eval()` function because of its slow performance, the one call per calculation is not a performance issue at all. The evaluated number is passed to the `format()` function for proper formatting (and setting of order of magnitude). In the meantime, the tolerance value is extracted from its array, and the combined string is plugged into the result text field (which is in a separate form, as described later):

```

// calculate resistance and tolerance values
function calcOhms() {
    var form = document.forms["rescalc"]
    var d1 = form.tensSelect.selectedIndex
    var d2 = form.onesSelect.selectedIndex
    var m = form.multiplierSelect.selectedIndex
    var t = form.toleranceSelect.selectedIndex
    var ohmage = (d1 * 10) + d2
    ohmage = eval("" + ohmage + "e" + multiplier[m])
    ohmage = format(ohmage)
    var tol = tolerance[t]
    document.forms["ouput"].result.value = ohmage + ", " + tol
}

```

Preloading images

As part of the script that runs when the document loads, the next group of statements precaches all possible images that can be displayed for the resistor art. For added scripting convenience, the color names are loaded into an array. With the help of that just-created array of color names, you then create another array (`imageDB`), which both generates `Image` objects for each image file and assigns a URL to each image. Notice an important subtlety about the index values being used to create each entry of the `imageDB` array: Each index is a `colorArray` entry, which is the name of the color. As you found out in Chapter 37, if you create an array

element with a named index, you must use that style of index to retrieve the data thereafter; you cannot switch arbitrarily between numeric indexes and names. As you see in a moment, this named index provides a critical link between the choices a user makes in the pop-up lists and the image objects being updated with the proper image file.

```
// pre-load all color images into image cache
var colorArray = new Array("Black","Blue","Brown","Gold","Gray",
    "Green","None","Orange","Red","Silver","Violet","White","Yellow")
var imageDB = new Array()
for (i = 0; i < colorArray.length; i++) {
    imageDB[colorArray[i]] = new Image(21,182)
    imageDB[colorArray[i]].src = colorArray[i] + ".gif"
}
```

The act of assigning a URL to the `src` property of an `Image` object instructs the browser to pre-load the image file into memory. This pre-loading happens as the document is loading, so another few seconds of delay won't be noticed by the user.

Changing images on the fly

The next four functions are invoked by their respective `SELECT` object's `onChange` event handler. For example, after a user makes a new choice in the first `SELECT` object (the “tens” value color selector), that `SELECT` object reference is passed to the `setTens()` function. Its job is to extract the text of the choice and use that text as the index into the `imageDB` array. Alternatively, the color name can also be assigned to the `VALUE` attribute of each `OPTION`, and the `value` property read here. You need this connection to assign the `src` property of that array entry to the `src` property of the image that you see on the page (defined in the following section). This assignment is what enables the images of the resistor to be updated instantaneously—just the one image “slice” affected by the user's choice in a `SELECT` object.

```
function setTens(choice) {
    var tensColor = choice.options[choice.selectedIndex].text
    document.tens.src = imageDB[tensColor].src
    calcOhms()
}
function setOnes(choice) {
    var onesColor = choice.options[choice.selectedIndex].text
    document.ones.src = imageDB[onesColor].src
    calcOhms()
}
function setMult(choice) {
    var multColor = choice.options[choice.selectedIndex].text
    document.mult.src = imageDB[multColor].src
    calcOhms()
}
function setTol(choice) {
    var tolColor = choice.options[choice.selectedIndex].text
    document.tol.src = imageDB[tolColor].src
    calcOhms()
}
```

The rest of the script for the Head portion of the document merely provides the statements that open the secondary window to display the introductory document:

```
function showIntro() {
    window.open("resintro.htm","",
        "WIDTH=400,HEIGHT=320,LEFT=100,TOP=100")
}
// end script hiding -->
</SCRIPT>
</HEAD>
```

Creating the SELECT objects

A comparatively lengthy part of the document is consumed with the HTML for the four SELECT objects. Notice, however, that the document contains an `onLoad` event handler in the `<BODY>` tag. This handler calculates the results of the currently selected choices whenever the document loads or reloads. If it weren't for this event handler, you would not see the resistor art when the document first appears. Also, because many browsers maintain their form controls' setting while the page is in history, a return to the page later must display the images previously selected in the form.

```
<BODY onLoad="calc0hms()"><CENTER>
<H1>Calculate <A HREF="javascript:showIntro()" onMouseOver="status='An
introduction to the resistor electronic component...';return true">Resistor</A>
Values from Color Codes</H1>
<FORM NAME="rescalc">
<SELECT NAME="tensSelect" onChange="setTens(this)">
    <OPTION SELECTED> Black
    <OPTION> Brown
    <OPTION> Red
    <OPTION> Orange
    <OPTION> Yellow
    <OPTION> Green
    <OPTION> Blue
    <OPTION> Violet
    <OPTION> Gray
    <OPTION> White
</SELECT>
<SELECT NAME="onesSelect" onChange="setOnes(this)">
    <OPTION SELECTED> Black
    <OPTION> Brown
    <OPTION> Red
    <OPTION> Orange
    <OPTION> Yellow
    <OPTION> Green
    <OPTION> Blue
    <OPTION> Violet
    <OPTION> Gray
    <OPTION> White
```

```

table += "<IMG SRC='resleft.gif' WIDTH=127 HEIGHT=182>" +
  "<IMG SRC='" + tensColor + ".gif' NAME='tens' WIDTH=21 " +
  "HEIGHT=182><IMG SRC='" + onesColor +
  ".gif' NAME='ones' WIDTH=21 HEIGHT=182>" +
  "<IMG SRC='" + multColor + ".gif' NAME='mult' WIDTH=21 " +
  "HEIGHT=182><IMG SRC='spacer.gif' WIDTH=17 HEIGHT=182>" +
  "<IMG SRC='" + tolColor + ".gif' NAME='tol' WIDTH=21 " +
  "HEIGHT=182><IMG SRC='resright.gif' WIDTH=127 HEIGHT=182>"
table += "</TD></TR></FORM></TABLE>"
document.write(table)
</SCRIPT>
<FONT SIZE=2>Illustration Copyright 1996 Danny Goodman. All Rights
Reserved.</FONT></CENTER>
</BODY>
</HTML>

```

As you can see, inside the images appear in one table cell (in the second row) that contains all seven image objects smashed against each other. To keep the images flush against each other, there can be no spaces or carriage returns between tags.

Further Thoughts

I am very pleased with the improvements to performance and perceived quality that swappable images and image precaching bring to the current version of this calculator. Images change crisply. Network latency is no longer an issue.

In the layout department, however, annoying differences still exist among different platforms. At one point in the design process, I considered trying to align the pop-up menus with images of the resistor (or callout line images), but the differences in platform rendering of pop-up menus made that idea impractical. At best, I now separate the three left SELECT objects from the right one by way of hard-coded spaces ();).

You should notice from this exercise that I look for ways to blend JavaScript object data structures with my own data's structure. For example, the SELECT objects serve multiple duties in these scripts. Not only does the text of each option point to an image file of the same name, but the index values of the same options are applied to the calculations. Things don't always work out that nicely, but whenever your scripts bring together user interface elements and data elements, look for algorithmic connections involving names or index integers that you can leverage to create elegant, concise code.

Application: Intelligent “Updated” Flags

It happens to every active Web user all the time: You visit a site periodically and never know for sure what material is new since your last visit. Often, Web page authors may flag items with “New” or “Updated” .gif images after they update those items themselves. But if you fail to visit the site over a few modification sessions, the only items you find flagged are those that are new as of the most recent update by the page’s author. Several new items from a few weeks back may be of vital interest to you, but you won’t have the time to look through the whole site in search of material that is more recent than *your* last visit. Even if the items display their modification dates, do you remember for sure the date and time of your last visit to the page?

As much as I might expect a CGI program and database on a Web site to keep track of my last visit, that really is asking a great deal of the Web site. Besides, not every Web site has the wherewithal to build such a database system — if it can even put up its own CGIs. Plus, some users won’t visit sites if they need to identify themselves or register.

After surveying the way scriptable browsers store cookie information and how time calculations are performed under NN3+ and IE4+, I found that a feasible alternative is to build this functionality into HTML documents and let the scripting manage the feature for users. The goal is to save in the visitor’s cookie file the date and time of the last visit to a page and then use that point as a measure against items that have an authorship time stamp in the HTML document.

The Cookie Conundrum

Managing the cookie situation in this application is a bit more complicated than you may think. The reason is that you have to take into account the possible ways visitors may come and go from your site while surfing the Web. You cannot

54

CHAPTER

In This Chapter

Temporary and persistent cookies

World time calculations

CGI-like intelligence

use just one cookie to store the last time a user visits the site, because you cannot predict when you should update that information with today's date and time. For example, if you have a cookie with the previous visit in it, you eventually need to store today's visit. But you cannot afford to overwrite the previous visit immediately (say in `onLoad`) because your scripts need that information to compare against items on the page not only right now, but even after the visitor vectors off from a link and comes back later. That also means you cannot update that last visit cookie solely via an `onUnload` event handler, because that, too, would overwrite information that you need when the visitor comes back a minute later.

To solve the problem, I devised a system of two cookies. One is written to the cookie that is given an expiration date of some time out in the future — the *hard cookie*, I call it. The other is a temporary *soft cookie*, which stays in cookie memory but is never written to the file. Such temporary cookies are automatically erased as the browser quits.

The hard cookie stores the time stamp when a visitor first loads the page since the last launch of the browser. In other words, the hard cookie contains a time stamp of the current visit. Before the previous entry is overwritten, however, it is copied into the soft cookie. That soft cookie maintains the time stamp of the previous visit and becomes the measure against which author time stamps in the HTML document are compared. To guard against inadvertent overwriting of both cookies, a function triggered by the document's `onLoad` event handler looks to see if the soft cookie has any data in it. If so, then the function knows that the visitor has been to this page in the current session and leaves the current settings alone. Thus, the visitor can come to the site and see what's new, vector off to some other location, and come back to see the same new items flagged and pick up from there.

One potential downside to this system is that if a user never quits the browser (or if the browser quits only by crashing), the cookies will never be updated. If you discover that a great deal of your users keep their computers and browsers running all the time, you can build in a kind of timeout that invalidates the soft cookie if the hard cookie is more than, say, 12 hours old.

Time's Not on Your Side

Thanks to over fifteen years' experience programming applications that involve tracking time, I am overly sensitive to the way computers and programming languages treat time on a global basis. This issue is a thorny one, what with the vagaries of Daylight Savings Time and time zones in some parts of the world that differ from their neighbors by increments other than whole hours.

In the case of working with time in JavaScript, you're at the mercy of how the browser and JavaScript interpreter deal with times as reflected by often imperfect operating systems. Those scripters who tried to script time-sensitive data in NN2 must have certainly experienced the wide fluctuations in the way each platform tracked time internally (over and above the outright bugs, especially in the Mac version of NN2). Fortunately, the situation improved significantly with NN3 and has only gotten better in all scriptable browsers. That's not to say all the bugs are gone, but at least they're manageable.

To accomplish a time tracking scheme for this application, I had to be aware of two times: the local time of the visitor and the local time of the page author. Making times match up in what can be widely disparate time zones, I use one time zone — GMT — as the reference point.

When a visitor arrives at the page, the browser needs to save that moment in time so that it can be the comparison measure for the *next* visit. Fortunately, whenever you create a new date object in JavaScript, it does so internally as the GMT date and time. Even though the way you attempt to read the date and time created by JavaScript shows you the results in your computer’s local time, the display is actually filtered through the time zone offset as directed by your computer’s time control panel. In other words, the millisecond value of every date object you create is maintained in memory in its GMT form. That’s fine for the visitor’s cookie value.

For the page author, however, I was presented with a different problem. Rather than force the author to convert the time stamps throughout the document to GMT, I wanted to let the author enter dates and times in local time. Aside from the fact that many people have trouble doing time zone conversions, looking at an existing item in the HTML with a local time stamp and instantly recognizing when that was last updated is much easier.

The problem, then, is how to let the visitor’s browser know what time the author’s time stamp is in GMT terms. To solve the issue, the author’s time stamp needs to include a reference to the author’s time zone relative to GMT. An Internet convention provides a couple of ways to do this: specifying the number of hours and minutes difference from GMT or, where supported by the browser, the abbreviation of the time zone. In JavaScript, you can create a new date object out of one of the specially formatted strings containing the date, time, and time zone. Three examples follow for the Christmas Eve dinner that starts at 6 p.m. in the Eastern Standard Time zone of North America:

```
var myDate = new Date("24 Dec 1997 23:00:00 GMT")
var myDate = new Date("24 Dec 1997 18:00:00 GMT-0500")
var myDate = new Date("24 Dec 1997 18:00:00 EST")
```

The first assumes you know the Greenwich Mean Time for the date and time that you want to specify. But if you don’t, you can use the GMT designation and offset value. The syntax indicates the date and time is in a time zone exactly five hours west of GMT (values to the east would be positive numbers) in `hhmm` format. Browsers also know all of the time zone abbreviations for North America (EST, EDT, CST, CDT, MST, MDT, PST, and PDT, where “S” is for standard time and “D” is for daylight time).

When a user visits a page with this application embedded in it, the visitor’s browser converts the author’s time stamp to GMT (with the help of the author’s zone offset parameter), so that both the author time stamp and last visit time stamp (in the soft cookie) are comparing apples to apples.

The Application

All of this discussion may make the application sound complicated. That may be true, internally. But the goal, as in most of the samples in this book, is to make the application easy to use in your site, even if you’re not sure how everything works inside.

The sample page described in this chapter and on the CD-ROM (`whatsnew.htm`) is pretty boring to look at, because the power all lies in the scripting that users don't see (see Figure 54-1). Though this figure may be the most uninspired graphic presentation of the book, the functionality may be the most valuable addition that you make to your Web site.

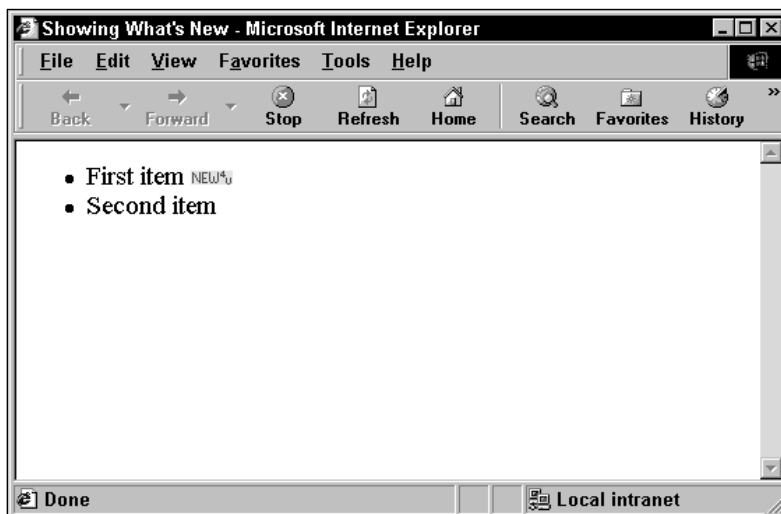

Figure 54-1: An item flagged as being new since my last visit to the page

When you first open the document (do so from a copy on your hard disk so that you can modify the author time stamp in a moment), all you see are the two items on the page without any flags. Although both entries have author time stamps that pre-date the time you're viewing the page, a soft cookie does not yet exist against which to compare those times. But the act of making the first visit to the page has created a hard cookie of the date and time that you first opened the page.

Quit the browser to get that hard cookie officially written to the cookie file. Then open the `whatsnew.htm` file in your script editor. Scroll to the bottom of the document, where you see the `<BODY>` tag and the interlaced scripts that time stamp anything that you want on the page. This application is designed to display a special `.gif` image that says "NEW 4U" whenever an item has been updated since your last visit.

Each interlaced script looks like this:

```
<SCRIPT LANGUAGE="JavaScript1.1">
document.write(newAsOf("12 Oct 2001 13:36:00 PDT"))
</SCRIPT>
```

By virtue of all scripts in this page being at the JavaScript 1.1 level, only those browsers so equipped will bother with the scripting (which also means that others lose out on this great visitor service). The `document.write()` method writes to the page whatever HTML comes back from the `newAsOf()` function. The parameter to the `newAsOf()` function is what holds the author time stamp and zone offset information. The time stamp value must be in the string format, as shown in the

preceding example, with the date and time following the exact order (“dd mmm yyyy hh:mm:ss”). Month abbreviations are in English (Jan, Feb, Mar, Apr, May, Jun, Jul, Aug, Sep, Oct, Nov, Dec).

As you see in the code that follows, the `newAsOf()` function returns an `` tag with the “NEW 4U” image if the author time stamp (after appropriate conversion) is later than the soft cookie value. This image can be placed anywhere in a document. For example, at my Web site, I sometimes place the image before a contents listing rather than at the end. This means, too, that if part of your page is written by `document.write()` methods, you can just insert the `newAsOf()` function call as a parameter to your own `document.write()` calls.

If you want to see the author time stamping work, edit one of the time stamps in the `whatsnew.htm` file to reflect the current time. Save the document and relaunch the browser to view the page. The item whose author time stamp you modified should now show the bright “NEW 4U” image.

The Code

The sample page starts by initializing three global variables that are used in the statements that follow. One variable is a Boolean value indicating whether the visitor has been to the page before. Another variable, `lastVisit`, holds the value of the soft cookie whenever the visitor is at this page. One other variable, `dateAdjustment`, is (unfortunately) necessary to take into account a date bug that persists in Macintosh versions of Navigator (times of new date objects can be off by one hour). I use this variable to automatically handle any discrepancies.

```
<HTML>
<HEAD>
<TITLE>Showing What's New</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
<!-- begin hiding

// globals
var repeatCustomer = false
var lastVisit = 0 // to hold date & time of previous access in GMT
milliseconds
var dateAdjustment = 0 // to accommodate date bugs on some platforms
```

For reading and writing cookie data, I use virtually the same cookie functions from the outline table of contents (see Chapter 52). The only difference is that the cookie writing function includes an expiration date, because I want this cookie to hang around in the cookie file for a while — at least until the next visit, whenever that may be.

```
// shared cookie functions
var mycookie = document.cookie
// read cookie data
function getCookieData(name) {
    var label = name + "="
    var labelLen = label.length
    var cLen = mycookie.length
    var i = 0
```

```

    while (i < cLen) {
        var j = i + labelLen
        if (mycookie.substring(i,j) == label) {
            var cEnd = mycookie.indexOf(";",j)
            if (cEnd == -1) {
                cEnd = mycookie.length
            }
            return unescape(mycookie.substring(j,cEnd))
        }
        i++
    }
    return ""
}

// write cookie data
function setCookieData(name,dateData,expires) {
    mycookie = document.cookie = name + "=" +
        dateData + "; expires=" + expires
}

```

Notice that the `setCookieData()` function still maintains a level of reusability by requiring a name for the cookie to be passed as a parameter along with the data and expiration date. I could have hard-wired the name into this function, but that goes against my philosophy of designing for reusability.

Next comes a function that figures out if any problems with JavaScript date accuracy exist on any platform. Essentially, the function creates two date objects, one to serve as a baseline. Even the baseline date can be bad (as it is on Mac versions of NN3), so to test against it, you want to use the second object to create another date using the first date object's own values as a parameter. If any major discrepancies occur, they will show up loud and clear.

```

// set dateAdjustment to accommodate Mac bug in Navigator 3
function adjustDate() {
    var base = new Date()
    var testDate = base
    testDate = testDate.toLocaleString()
    testDate = new Date(testDate)
    dateAdjustment = testDate.getTime() - base.getTime()
}

```

In truth, this function always shows some adjustment error, because both the baseline date and test date cannot be created simultaneously. Even in an accurate system, the two will vary by some small number of milliseconds. For the purposes here, this amount of variance is insignificant.

Setting the stage

Functions in the next part of the script get your cookies all in a row. The first function (`saveCurrentVisit()`) deals with the visitor's local time, converting it to a form that will be useful on the next visit. Although one of the local variables is called `nowGMT`, all the variable does is take the new date object and convert it to the GMT milliseconds value (minus any `dateAdjustment` value) by invoking the `getTime()` method of the date object. I use this name in the variable to help me remember what the value represents:

```
// write date of current visit (in GMT time) to cookie
function saveCurrentVisit() {
    var visitDate = new Date()
    var nowGMT = visitDate.getTime() - dateAdjustment
    var expires = nowGMT + (180 * 24 * 60 * 60 * 1000)
    expires = new Date(expires)
    expires = expires.toGMTString()
    setCookieData("lastVisit", nowGMT, expires)
}
```

From the current time, I create an expiration date for the cookie. The example shows a date roughly six months (180 days, to be exact) from the current time. I leave the precise expiration date up to your conscience and how long you want the value to linger in a user’s cookie file.

The final act of the `saveCurrentVisit()` function is to pass the relevant values to the function that actually writes the cookie data. I assign the name `lastVisit` to the cookie. If you want to manage this information for several different pages, then assign a different cookie name for each page. This setup can be important in case a user gets to only part of your site during a visit. On the next visit, the code can point to page-specific newness of items.

The bulk of what happens in this application takes place in an initialization function. All the cookie swapping occurs there, as well as the setting of the `repeatCustomer` global variable value:

```
// set up global variables and establish whether user is a newbie
function initialize() {
    var lastStoredVisit = getCookieData("lastVisit")
    var nextPrevStoredVisit = getCookieData("nextPrevVisit")

    adjustDate()

    if (!lastStoredVisit) {
        // never been here before
        saveCurrentVisit()
        repeatCustomer = false
    } else {
        // been here before...
        if (!nextPrevStoredVisit) {
            // but first time this session
            // so set cookie only for current session
            setCookieData("nextPrevVisit", lastStoredVisit, "")
            lastVisit = parseFloat(lastStoredVisit)
            saveCurrentVisit()
            repeatCustomer = true
        } else {
            // back again during this session (perhaps reload or Back)
            lastVisit = parseFloat(nextPrevStoredVisit)
            repeatCustomer = true
        }
    }
}
initialize()
```

The first two statements retrieve both hard (`lastVisit`) and soft (`nextPrevVisit`) cookie values. After calling the function that sets any necessary date adjustment, the script starts examining the values of the cookies to find out where the visitor stands upon coming to the page.

The first test is whether the person has ever been to the page before. You do this by checking whether a hard cookie value (which would have been set in a previous visit) exists. If no such cookie value exists, then the current visit time is written to the hard cookie and `repeatCustomer` is set to `false`. These actions prepare the visitor's cookie value for the *next* visit.

Should a user already be a repeat customer, you have to evaluate whether this visit is the user's first visit since launching the browser. You do that by checking for a value in the soft cookie. If that value doesn't exist, then it means the user is here for the first time "today." You then grab the hard cookie and drop it into the soft cookie before writing today's visit to the hard cookie.

For repeat customers who have been here earlier in this session, you update the `lastVisit` global variable from the cookie value. The variable value will have been destroyed when the user left the page just a little while ago, whereas the soft cookie remains intact, enabling you to update the variable value now.

Outside of the function definition, the script automatically executes the `initialize()` function by that single statement. This function runs every time the page loads.

The date comparison

Every interlaced script in the body of the document calls the `newAsOf()` function to find out if the author's time stamp is after the last visit of the user to the page. This function is where the time zone differences between visitor and author must be neutralized so that a valid comparison can be made:

```
function newAsOf(authorDate) {
    authorDate = new Date(authorDate)
    var itemUpdated = authorDate.getTime()
    return ((itemUpdated > lastVisit) && repeatCustomer) ?
        "<IMG SRC='updated.gif' HEIGHT=10 WIDTH=30>" : ""
}
// end hiding -->
</SCRIPT>
</HEAD>
```

As you saw earlier, calls to this function require one parameter: a specially formatted date string that includes time zone information. The first task in the function is to re-cast the author's date string to a date object. You reuse the variable name (`authorDate`) because its meaning is quite clear. The date object created here is stored internally in the browser in GMT time, relative to the time zone data supplied in the parameter. To assist in the comparison against the `lastVisit` time (stored in milliseconds), the `getTime()` method converts `authorDate` to GMT milliseconds.

The last statement of the function is a conditional expression that returns the `` tag definition for the "NEW 4U" image only if the author's time stamp is later than the soft cookie value and the visitor has been here before. Otherwise, the

function returns an empty string. Any `document.write()` method that calls this function and executes via this branch writes an empty string—nothing—to the page.

A live <BODY>

For the sample document, I have you create a simple bulleted list of two entries, imaginatively called “First item” and “Second item.” Interlaced into the HTML are scripts that are ready to insert the “NEW 4U” image if the author time stamp is new enough:

```
<BODY>
<UL>
<LI>First item
<SCRIPT LANGUAGE="JavaScript1.1">
<!--
document.write(newAsOf("20 Oct 2000 09:36:00 PDT"))
//-->
</SCRIPT>
<LI>Second item
<SCRIPT LANGUAGE="JavaScript1.1">
<!--
document.write(newAsOf("18 Oct 2000 17:40:00 PDT"))
//-->
</SCRIPT>
</UL>
</BODY>
</HTML>
```

All these script tags make the HTML a bit hard to read, but I believe the functionality is worth the effort. Moreover, by specifying the JavaScript 1.1 language attribute, the scripts are completely ignored by older JavaScript-enabled browsers. Only the now very rare, exceedingly brain-dead browsers, which get tripped up on the SGML comment lines, would know that something out of the ordinary is taking place.

Further Thoughts

You can, perhaps, go overboard with the way that you use this technique at a Web site. Like most features in JavaScript, I recommend using it in moderation and confining the flags to high-traffic areas that repeat visitors frequent. One hazard is that you can run out of the 20 cookies if you have too many page-specific listings.

You can share the same cookie among documents in related frames. Locate all the functions from the script in this chapter’s Head section into a Head section of a framesetting document. Then, modify the call to the `newAsOf()` function by pointing it to the parent:

```
document.write(parent.newAsOf("18 Oct 2000 17:40:00 PDT"))
```

That way, one cookie can take care of all documents that you display in that frameset.

Application: Decision Helper

The list of key concepts for this chapter's application looks like the grand finale to a fireworks show. As JavaScript implementations go, the application is, in some respects, over the top, yet not out of the question for presenting a practical interactive application on a Web site without any server programming.

The Application

I wanted to implement a classic application (listed at the right) often called a *decision support system*. My experience with the math involved here goes back to the first days of Microsoft Excel. Rather than design a program that had limited appeal (covering only one possible decision tree), I set out to make a completely user-customizable decision helper. All the user has to do is enter values into fields on a series of screens; the program performs the calculations to let the user know how the various choices rank against each other.

Although I won't be delving too deeply into the math inside this application, you will find it helpful to understand how a user approaches this program and what the results look like. The basic scenario is a user who is trying to evaluate how well a selection of choices measure up to his or her expectations of performance. User input includes:

- ◆ The name of the decision
- ◆ The names of up to five alternatives (people, products, ideas, and so on)
- ◆ The factors or features of concern to the user
- ◆ The importance of each of the factors to the user
- ◆ A user ranking of the performance of every alternative in each factor

55

CHAPTER

In This Chapter

Multiple frames

Multiple-document applications

Multiple windows

Persistent storage (cookies)

Scripted image maps

Scripted charts

What makes this kind of application useful is that it forces the user to rate and weigh a number of often-conflicting factors. By assigning hard numbers to these elements, the user leaves the difficult process of figuring out the weights of various factors to the computer.

Results come in the form of floating-point numbers between 0 and 100. As an extra touch, I've added a graphical charting component to the results display.

The Design

With so much user input necessary for this application, conveying the illusion of simplicity was important. Rather than lump all text objects on a single scrolling page, I decided to break them into five pages, each consisting of its own HTML document. As an added benefit, I could embed information from early screens into the HTML of later screens, rather than having to create all changeable items out of text objects so that the application would work with older browsers. This “good idea” presented one opportunity and one rather large challenge.

The opportunity was to turn the interface for this application into something resembling a multimedia application using multiple frames. The largest frame would contain the forms the user fills out as well as the results page. Another frame would contain a navigation panel with arrows for moving forward and backward through the sequence of screens, plus buttons for going back to a home page and getting information about the program. I also thought a good idea would be to add a frame that provides instructions or suggestions for the users at each step. And so, the three-frame window was born, as shown in the first entry screen in Figure 55-1.

Figure 55-1: The Decision Helper window consists of three frames.

Using a navigation bar also enables me to demonstrate how to script a client-side image map — not an obvious task with JavaScript.

On the challenge side of this design, finding a way to maintain data globally as the user navigates from screen to screen was necessary. Every time one of the entry pages unloads, none of its text fields is available to a script. My first attack at this problem was to store the data as global variable data (mostly arrays) in the parent document that creates the frames. Because JavaScript enables you to reference any parent document's object, function, or variable (by preceding the reference with `parent`), I thought this task would be a snap. A nasty bug in Navigator 2 (the prominent browser when this application was first developed) got in the way at the time: If a document in any child window unloaded, the variables in the parent window got jumbled. The other hazard here is that a reload of the frameset could erase the current state of those variables.

My next hope was to use the `document.cookie` as the storage bin for the data. A major problem I faced was that this program needs to store a total of 41 individual data points, yet no more than 20 uniquely named cookies can be allotted to a given domain. But the cookie proved to be the primary solution for this application (although see the “Further Thoughts” section at the end of the chapter about a non-cookie version on your CD-ROM). For some of the data points (which are related in an array-like manner), I fashioned my own data structures so that one named cookie could contain up to five related data points. That reduced my cookie demands to 17.

The Files

Before I get into the code, let me explain the file structure of this application. Table 55-1 gives a rundown of the files used in the Decision Helper.

Table 55-1 Files Comprising the Decision Helper Application

<i>File</i>	<i>Description</i>
<code>index.htm</code>	Framesetting parent document
<code>dhNav.htm</code>	Navigation bar document which contains some scripting
<code>dhNav.gif</code>	Image displayed in <code>dhNav.htm</code>
<code>dh1.htm</code>	First Decision Helper entry page
<code>dh2.htm</code>	Second Decision Helper entry page
<code>dh3.htm</code>	Third Decision Helper entry page
<code>dh4.htm</code>	Fourth Decision Helper entry page
<code>dh5.htm</code>	Results page
<code>chart.gif</code>	Tiny image file used to create bar charts in <code>dh5.htm</code>
<code>dhHelp.htm</code>	Sample data and instructions document for lower-right frame
<code>dhAbout.htm</code>	Document that loads into a second window

A great deal of interdependence exists among these files. As you see later, assigning the names to some of these files was strategic for the implementation of the image map.

The Code

With so many JavaScript-enhanced HTML documents in this application, you can expect a great deal of code. To best grasp what's going on here, first try to understand the structure and interplay of the documents, especially the way the entry pages rely on functions defined in the parent document. My goal in describing this structure is not to teach you how to implement this application, but rather how to apply the lessons I learned while building this application to the more complex ideas that may be aching to get out of your head and into JavaScript.

index.htm

Taking a top-down journey through the JavaScript and HTML of the Decision Helper, start at the document that loads the frames. Unlike a typical framesetting document, however, this one contains JavaScript code in its Head section — code that many other documents rely on.

```
<HTML>
<HEAD>
<TITLE>Decision Helper</TITLE>
```

An important consideration to remember is that in a multiple-frame environment, the title of the parent window's document is the name that appears in the window's title bar, no matter how many other documents are open inside its subframes.

The first items of the script control a global variable, `currTitle`, which is set by a number of the subsidiary files as the user navigates through the application. This variable ultimately helps the navigation bar buttons do their jobs correctly. Because this application relies on the `document.cookie` so heavily, the cookie management functions (slightly modified versions of Bill Dortch's Cookie Functions — Chapter 18) are located in the parent document so they load only once. I simplified the cookie writing function because this application uses default settings for pathname and expiration. With no expiration date, the cookies don't survive the current browser session, which is perfect for this application.

```
<SCRIPT LANGUAGE="JavaScript">
<!-- start
// global variable settings of current dh document number
var currTitle = ""
function setTitleVar(titleVal) {
    currTitle = "" + titleVal
}
function getCookieVal (offset) {
    var endstr = mycookie.indexOf(";", offset)
    if ((" + endstr) == "" || endstr == -1)
        endstr = mycookie.length
    return unescape(mycookie.substring(offset, endstr))
}
```

```

function getCookie (name) {
    var arg = name + "=";
    var alen = arg.length;
    var clen = mycookie.length;
    var i = 0;
    while (i < clen) {
        var j = i + alen;
        if (mycookie.substring(i, j) == arg) {
            return getCookieVal (j);
        }
        i = mycookie.indexOf(" ", i) + 1;
        if (i == 0) break;
    }
    return null;
}

var mycookie = document.cookie
function setCookie (name, value) {
    mycookie = document.cookie = name + "=" + escape (value) + ";"
}

```

When this application loads (or a user elects to start a new decision), it's important to grab the cookies you need and initialize them to basic values that the entry screens will use to fill entry fields when the user first visits them. All statements inside the `initializeCookies()` function call the `setCookie()` function, defined in the preceding listing. The parameters are the name of each cookie and the initial value—mostly empty strings. Before going on, study the cookie labeling structure carefully. I refer to it often in discussions of other documents in this application.

```

function initializeCookies() {
    setCookie("decName","")
    setCookie("alt0","")
    setCookie("alt1","")
    setCookie("alt2","")
    setCookie("alt3","")
    setCookie("alt4","")
    setCookie("factor0","")
    setCookie("factor1","")
    setCookie("factor2","")
    setCookie("factor3","")
    setCookie("factor4","")
    setCookie("import","0")
    setCookie("perf0","")
    setCookie("perf1","")
    setCookie("perf2","")
    setCookie("perf3","")
    setCookie("perf4","")
}

```

The following functions should look familiar to you. They were borrowed either wholesale or with minor modification from the data-entry validation section of the

Social Security number database lookup in Chapter 50. I'm glad I wrote these as generic functions, making them easy to incorporate into this script. Because many of the entry fields on two screens must be integers between 1 and 100, I brought the data validation functions to the parent document rather than duplicating them in each of the subdocuments.

```
// JavaScript sees numbers with leading zeros as octal values, so
// strip zeros
function stripZeros(inputStr) {
    return (parseFloat(inputStr, 10)).toString()
}

// general purpose function to see if a suspected numeric input
// is a positive integer
function isNumber(inputStr) {
    for (var i = 0; i < inputStr.length; i++) {
        var oneChar = charAt(i)
        if (oneChar < "0" || oneChar > "9") {
            return false
        }
    }
    return true
}

// function to determine if value is in acceptable range for this
// application
function inRange(inputStr) {
    num = parseInt(inputStr)
    if (num < 1 || num > 100) {
        return false
    }
    return true
}
```

To control the individual data-entry validation functions in the master controller, I again was able to borrow heavily from the application in Chapter 50.

```
// Master value validator routine
function isValid(inputStr) {
    if (inputStr != "" ) {
        inputStr = stripZeros(inputStr)
        if (!isNumber(inputStr)) {
            alert("Please make sure entries are numbers only.")
            return false
        } else {
            if (!inRange(inputStr)) {
                alert("Entries must be numbers between 1 and 100. Try another
value.")
                return false
            }
        }
    }
    return true
}
```

Each of the documents containing entry forms retrieves and stores information in the cookie. Because all cookie functions are located in the parent document, it simplifies coding in the subordinate documents to have functions in the parent document acting as interfaces to the primary cookie functions. For each category of data stored as cookies, the parent document has a pair of functions for getting and setting data. The calling statements pass only the data to be stored when saving information; the interface functions handle the rest, such as storing or retrieving the cookie with the correct name.

In the following pair of functions, the decision name (from the first entry document) is passed back and forth between the cookie and the calling statements. Not only must the script store the data, but if the user returns to that screen later for any reason, the entry field must retrieve the previously entered data.

```
function setDecisionName(str) {
    setCookie("decName",str)
}
function getDecisionName() {
    return getCookie("decName")
}
```

The balance of the storage and retrieval pairs does the same thing for their specific cookies. Some cookies are named according to index values (`factor1`, `factor2`, and so on), so their cookie-accessing functions require parameters for determining which of the cookies to access, based on the request from the calling statement. Many of the cookie retrieval functions are called to fill in data in tables of later screens during the user's trip down the decision path.

```
// values for alternatives
function setAlternative(i,str) {
    setCookie("alt" + i,str)
}
function getAlternative(i) {
    return getCookie("alt" + i)
}

// values for decision factors
function setFactor(i,str) {
    setCookie("factor" + i,str)
}
function getFactor(i) {
    return getCookie("factor" + i)
}

// values for importance (decision factor weights)
function setImportance(str) {
    setCookie("import",str)
}
function getImportance(i) {
    return getCookie("import")
}
```

```
// values for performance ratings
function setPerformance(i,str) {
    setCookie("perf" + i,str)
}
function getPerformance(i) {
    return getCookie("perf" + i)
}
```

One sequence of code that runs when the parent document loads is the one that looks to see if a cookie structure is set up. If no such structure is set up (the retrieval of a designated cookie returns a `null` value), the script initializes all cookies via the function described earlier.

```
if (getDecisionName() == null) {
    initializeCookies()
}
// end -->
</SCRIPT>
</HEAD>
```

The balance of the parent document source code defines the frameset for the browser window. It establishes some hard-wired pixel sizes for the navigation panel. This ensures that the entire `.gif` file is visible whenever the frameset loads, without a ton of unwanted white space if the browser window is large.

```
<FRAMESET ROWS="250,*">
  <FRAMESET COLS="104,*">
    <FRAME NAME="navBar" SRC="dhNav.htm" SCROLLING=no
      MARGINHEIGHT=2 MARGINWIDTH=1>
    <FRAME NAME="entryForms" SRC="dh1.htm">
  </FRAMESET>
  <FRAMESET ROWS="100%">
    <FRAME NAME="instructions" SRC="dhHelp.htm">
  </FRAMESET>
</FRAMESET>
</HTML>
```

I learned an important lesson about scripting framesets along the way. Older browsers, especially NN through Version 4, do not respond to changes in frameset-size attributes through a simple reload of the page. I found it necessary to reopen the frameset file from time to time. I also found it necessary to sometimes quit early Navigators altogether and relaunch it to make some changes visible. Therefore, if you seem to be making changes, but reloading the frameset doesn't make the changes appear, try reopening or — as a last resort — quitting the browser.

dhNav.htm

Because of its crucial role in controlling the activity around this program, look into the navigation bar's document next. To accomplish the look and feel of a multimedia program, this document was designed as a client-side image map that has four regions scripted corresponding to the locations of the four buttons (see Figure 55-1). One function is connected to each button.

The first function is linked to the graphical Home button. For the listing here, I just present an alert dialog box replicating the action of navigating back to a real Web site's home page.

```
<HTML>
<HEAD>
<TITLE>Navigation Bar</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!-- start
function goHome() {
    alert("Navigate back to home page on a real site.")
}
```

Each of the arrow navigation buttons brings the user to the next or previous entry screen in the sequence. To facilitate this without building tables of document titles and names, you call upon the `currTitle` global variable in the parent document. This value contains an integer in the range between 1 and 5, corresponding to the main content documents, `dh1.htm`, `dh2.htm`, and so on. As long as the offset number is no higher than the next-to-last document in the sequence, the `goNext()` function increments the index value by one and concatenates a new location for the frame. At the same time, the script advances the help document (in the bottom frame) to the anchor corresponding to the chosen entry screen by setting the `location.hash` property of that frame. Similar action navigates to the previous screen of the sequence through the `goPrev()` function. This time, the index value is decremented by one, and an alert warns the user if the current page is already the first in the sequence.

```
function goNext() {
    var currOffset = parseInt(parent.currTitle)
    if (currOffset <= 4) {
        ++currOffset
        parent.entryForms.location.href = "dh" + currOffset + ".htm"
        parent.instructions.location.hash = "help" + currOffset
    } else {
        alert("This is the last form.")
    }
}
function goPrev() {
    var currOffset = parseInt(parent.currTitle)
    if (currOffset > 1) {
        --currOffset
        parent.entryForms.location.href = "dh" + currOffset + ".htm"
        parent.instructions.location.hash = "help" + currOffset
    } else {
        alert("This is the first form.")
    }
}
```

Clicking the Info button displays a smaller window containing typical About-box data for the program (see Figure 55-2).

```
function goInfo() {
    var newWindow =
```

```

        window.open("dhAbout.htm", "", "HEIGHT=250,WIDTH=300")
    }
    // end -->
</SCRIPT>
</HEAD>

```

The Body of the navigation document contains the part that enables you to script a client-side image map. Mouse `click` events weren't available to AREA elements until Version 4 browsers, so to let these image maps work with older versions, mouse action is converted to script action by assigning a `javascript:` pseudo-URL to the `HREF` attribute for each AREA element. Instead of pointing to an entirely new URL (as AREA elements usually work), the attributes point to the JavaScript functions defined in the Head portion of this document. After a user clicks the rectangle specified by an `<AREA>` tag, the browser invokes the function instead.

Figure 55-2: The About Decision Helper screen appears in a separate window.

```

<BODY>
<MAP NAME="navigation">
<AREA SHAPE="RECT" COORDS="23,22,70,67" HREF="javascript:goHome()">
<AREA SHAPE="RECT" COORDS="25,80,66,116" HREF="javascript:goNext()">
<AREA SHAPE="RECT" COORDS="24,125,67,161" HREF="javascript:goPrev()">
<AREA SHAPE="RECT" COORDS="35,171,61,211" HREF="javascript:goInfo()">
</MAP>
<IMG SRC="dhNav.gif" BORDER HEIGHT=240 WIDTH=96 ALIGN="left"
USEMAP="#navigation">
</BODY>
</HTML>

```

Although not shown here, you can assign `onMouseOver` event handlers to each AREA element for NN3+ and IE4+ to display a friendly message about the action of each button.

dh1.htm

Of the five documents that display in the main frame, `dh1.htm` is the simplest (refer to Figure 55-1). It contains a single entry field in which the user is invited to enter the name for the decision.

Only one function adorns the Head. This function summons one of the cookie interface functions in the parent window. A test is located here in case there is a problem with initializing the cookies. Rather than show `null` in the field, the conditional expression substitutes an empty string.

```
<HTML>
<HEAD>
<TITLE>DH1</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!-- start
function loadDecisionName() {
    var result = parent.getDecisionName()
    result = (result == null) ? "" : result
    document.forms[0].decName.value = result
}
// end -->
</SCRIPT>
</HEAD>
```

After the document loads, it performs three tasks (in the `onLoad` event handler). The first task is to set the global variable in the parent to let it know which number of the five main documents is currently loaded. Next, the script must fill the field with the decision name stored in the cookie. This task is important because users will want to come back to this screen to review what they entered previously. A third statement in the `onLoad` event handler sets the focus of the entire browser window to the one text object. This task is especially important in a multi-frame environment, such as this design. After a user clicks on the navigation panel, that frame has the focus. To begin typing into the field, the user has to tab (repeatedly) or click the text box to give the text box focus for typing. By setting the focus in the script when the document loads, you save the user time and aggravation.

```
<BODY onLoad="parent.setTitleVar(1);loadDecisionName();
document.forms[0].decName.focus()">
<H2>The Decision Helper</H2>
<HR>
<H4>Step 1 of 5: Type the name of the decision you're making. Then click the
"Next" arrow.</H4>
```

In the text field itself, an `onChange` event handler saves the value of the field in the parent's cookie for the decision name. No special Save button or other instruction is necessary here because any navigation that the user does via the navigation bar automatically causes the text field to lose focus and triggers the `onChange` event handler.

```
<CENTER>
<FORM>
Decision Name:
<INPUT TYPE="text" NAME="decName" SIZE="40"
onChange="parent.setDecisionName(this.value)">
</FORM>
</CENTER>
</BODY>
</HTML>
```

The copy of this file on the CD-ROM also has code that allows for plugging in sample data (as seen on my Web site) and a (commented out) textarea object that you can use for debugging cookie data.

dh2.htm

For the second data-entry screen (shown in Figure 55-3), five fields invite the user to enter descriptions of the alternatives under consideration. As with the decision name screen, the scripting for this page must both retrieve and save data displayed or entered in the fields.

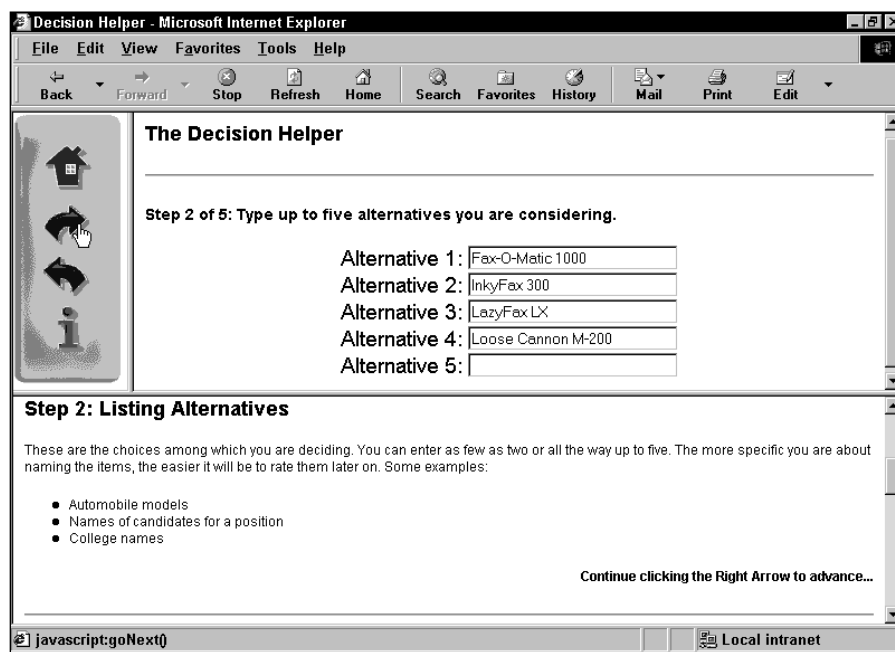

Figure 55-3: The second data-entry screen

In one function, the script retrieves the alternative cookies (five total) and stuffs them into their respective text fields (as long as their values are not `null`). This function script uses a `for` loop to cycle through all five items — a common process throughout this application. Whenever a cookie is one of a set of five, the parent function has been written (in the following example) to store or extract a single cookie, based on the index value. Text objects holding like data (defined in the following listing) are all assigned the same name, so that JavaScript lets you treat them as array objects — greatly simplifying the placement of values into those fields inside a `for` loop.

```
<HTML>
<HEAD>
<TITLE>DH2</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

<!-- start
function loadAlternatives() {
    for (var i = 0; i < 5; i++) {
        var result = parent.getAlternative(i)
        result = (result == null) ? "" : result
        document.forms[0].alternative[i].value = result
    }
}
// end -->
</SCRIPT>
</HEAD>

```

After the document loads, the document number is sent to the parent's global variable, its fields are filled by the function defined in the Head, and the first field is handed the focus to assist the user in entering data the first time.

```

<BODY onLoad="parent.setTitleVar(2);loadAlternatives();
document.forms[0].alternative[0].focus()">
<H2>The Decision Helper</H2>
<HR>
<H4>Step 2 of 5: Type up to five alternatives you are considering.</H4>

```

Any change that a user makes to a field is stored in the corresponding cookie. Each `onChange` event handler passes its indexed value (relative to all like-named fields) plus the value entered by the user as parameters to the parent's cookie-saving function.

```

<CENTER>
<FORM>
Alternative 1:
<INPUT TYPE="text" NAME="alternative" SIZE="25"
onChange="parent.setAlternative(0,this.value)"><BR>
Alternative 2:
<INPUT TYPE="text" NAME="alternative" SIZE="25"
onChange="parent.setAlternative(1,this.value)"><BR>
Alternative 3:
<INPUT TYPE="text" NAME="alternative" SIZE="25"
onChange="parent.setAlternative(2,this.value)"><BR>
Alternative 4:
<INPUT TYPE="text" NAME="alternative" SIZE="25"
onChange="parent.setAlternative(3,this.value)"><BR>
Alternative 5:
<INPUT TYPE="text" NAME="alternative" SIZE="25"
onChange="parent.setAlternative(4,this.value)"><BR>
</BODY>
</HTML>

```

dh3.htm

With the third screen, the complexity increases a bit. Two factors contribute to this increase in difficulty. One is that the limitation on the number of cookies available for a single domain forces you to join into one cookie the data that might normally be distributed among five cookies. Second, with the number of text

objects on the page (see Figure 55-4), it becomes more efficient (from the standpoint of tedious HTML writing) to let JavaScript deploy the fields. The fact that two sets of five related fields exist facilitates using `for` loops to lay out and populate them.

One initial function here is reminiscent of `Head` functions in previous entry screens. This function retrieves a single factor cookie from the set of five cookies.

```
<HTML>
<HEAD>
<TITLE>DH3</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!-- start
function getdh3Factor (i) {
    var result = parent.getFactor(i)
    if (result == null) {
        return ""
    }
    return result
}
}
```

The Decision Helper

Step 3 of 5: List the factors that will influence your decision, and assign a weight (from 1 to 100) to signify the importance of each factor in your decision.

Factor 1-->	Cost	80	<--Weight 1
Factor 2-->	Size	40	<--Weight 2
Factor 3-->	Paper Handling	60	<--Weight 3
Factor 4-->	Warranty	70	<--Weight 4
Factor 5-->			<--Weight 5

Step 3: Assigning Factors and Weights

Factors are the kinds of items you might find in a product feature checklist. But they can also be subjective items, such as the prestige you might attach to the neighborhoods in which houses you're considering are located. Whatever you enter here, the items should be factors that you can measure either by some hard measure (e.g., the size of a computer model's hard disk) or by subjective measure (e.g., what the buzz is around campus about a potential college course's prospects are for meeting members of the opposite sex).

Weights are a measure of how important a particular factor is to you. For instance, when buying a car, interior space may be very important to you (rating, say, a 90), but fuel economy is further down the list of considerations (rating perhaps a 30). Each value you enter here is independent of the others: consider each factor individually, and assign a weight value between 1 and 100.

Continue clicking the Right Arrow to advance...

javascript:goNext() Local intranet

Figure 55-4: Screen for entering decision factors and their weights

Values for the five possible weight entries are stored together in a single cookie. To make this work, I had to determine a data structure for the five “fields” of a single cookie “record.” Because all entries are integers, I can choose any nonnumeric character. I arbitrarily selected the period.

```

function setdh3Importance () {
    var oneRecord = ""
    for (var i = 0; i < 5; i++) {
        var dataPoint = document.forms[0].importance[i].value
        if (!parent.isValid(dataPoint)) {
            document.forms[0].importance[i].focus()
            document.forms[0].importance[i].select()
            return
        }
        oneRecord += dataPoint + "."
    }
    parent.setImportance(oneRecord)
    return
}

```

The purpose of the `setdh3Importance()` function is to assemble all five values from the five Weight entry fields (named “importance”) into a period-delimited record that is ultimately sent to the cookie for safekeeping. Another of the many `for` loops in this application cycles through each of the fields, checking for validity and then appending the value with its trailing period to the variable (`oneRecord`) that holds the accumulated data. As soon as the loop finishes, the entire record is sent to the parent function for storage.

Although the function shows two `return` statements, the calling statement does not truly expect any values to be returned. Instead, I use the `return` statement inside the `for` loop as a way to break out of the `for` loop without any further execution whenever an invalid entry is found. Just prior to that, the script sets the focus and select to the field containing the invalid entry. JavaScript, however, is sensitive to the fact that a function with a `return` statement in one possible outcome doesn’t have a `return` statement for other outcomes (an error message to this effect appears in some browsers if you try the function without balanced returns). By putting a `return` statement at the end of the function, all other possibilities are covered to the browser’s satisfaction.

The inverse of storing the weight entries is retrieving them. Because the `parent.getImportance()` function returns the entire period-delimited record, this function must break apart the pieces and distribute them into their corresponding Weight fields. A combination of string methods determines the offset of the period and how far the data extraction should go into the complete record. Before the `for` loop repeats each time, it is shortened by one “field’s” data. In other words, as the `for` loop executes, the copy of the cookie data returned to this function is pared down one entry at a time as each entry is stuffed into its text object for display.

```

function getdh3Importance () {
    var oneRecord = parent.getImportance()
    if (oneRecord != null) {
        for (var i = 0; i < 5; i++) {
            var recLen = oneRecord.length
            var offset = oneRecord.indexOf(".")
            var dataPoint = (offset >= 0) ?
                oneRecord.substring(0,offset) : ""
            document.forms[0].importance[i].value = dataPoint
            oneRecord = oneRecord.substring(offset+1,recLen)
        }
    }
}

```

```

    }
  }
}

// end -->
</SCRIPT>
</HEAD>

```

Upon loading the document, the only tasks that the `onLoad` event handler need to do are to update the parent global variable about the document number and to set the focus to the first entry field of the form.

```

<BODY onLoad=" parent.setTitleVar(3);document.forms[0].factor[0].focus()">
<H2>The Decision Helper</H2>
<HR>
<H4>Step 3 of 5: List the factors that will influence your decision,
and assign a weight (from 1 to 100) to signify the importance of each factor in
your decision.</H4>

```

Assembling the HTML for the form and its ten data-entry fields needs only a few lines of JavaScript code. Performed inside a `for` loop, the script assembles each line of the form, which consists of a label for the Factor (and its number), the factor input field, the importance input field, and the label for the Weight (and its number). A `document.write()` method writes each line to the document.

```

<SCRIPT LANGUAGE="JavaScript">
<!-- start
var output = "<CENTER><FORM>"
for (i = 0; i < 5; i++) {
  output += "Factor " + (i+1) +
    "--><INPUT TYPE='text' NAME='factor' SIZE='25' "
  var eHandler = " onChange=\ 'parent.setFactor(" + i + ",this.value)\ ' "
  output += eHandler + "VALUE=" + getdh3Factor (i) + ">"

  output += "<INPUT TYPE='text' NAME='importance' SIZE='3' "
  var eHandler = " onChange=\ setdh3Importance ()\ ' "
  output += eHandler + "VALUE=' '>"
  output += "--Weight " + (i+1) + "<BR>"
  document.write(output)
  output = ""
}
document.write("</FORM></CENTER>")
getdh3Importance ()
// end -->
</SCRIPT>
</BODY>
</HTML>

```

Each of the scripted text objects has an event handler. Notice that each event handler is first defined as a variable on a statement line just above its insertion into the string being assembled for the `INPUT` object definition. One reason for this fact is that the nested quote situation gets quite complex when you are doing these tasks all in one massive assignment statement. Rather than mess with matching

several pairs of deeply nested quotes, I found it easier to break out one portion (the event handler definition) as a variable value and then insert that preformatted expression into the concatenated string for the INPUT definition.

Notice, too, how the different ways of storing the data in the cookies influence the ways the existing cookie data is filled into the fields as the page draws itself. For the factors, which have one cookie per factor, the VALUE attribute of the field is set with a specific indexed call to the parent factor cookie retriever, one at a time. But for the importance values, which are stored together in the period-delimited chunk, a separate function call (`getdh3Importance()`) executes after the fields are already drawn (with initial values of empty strings) and fills all the fields in a batch operation.

dh4.htm

Step 4 of the decision process (shown in Figure 55-5) is the most complex step because of the sheer number of entry fields: 25 in all. Notice that this screen retrieves data from two of the previous screens (or rather from the cookies preserving the entries) and embeds the values into the fixed parts of the table. All these tasks are possible when you create those tables with JavaScript.

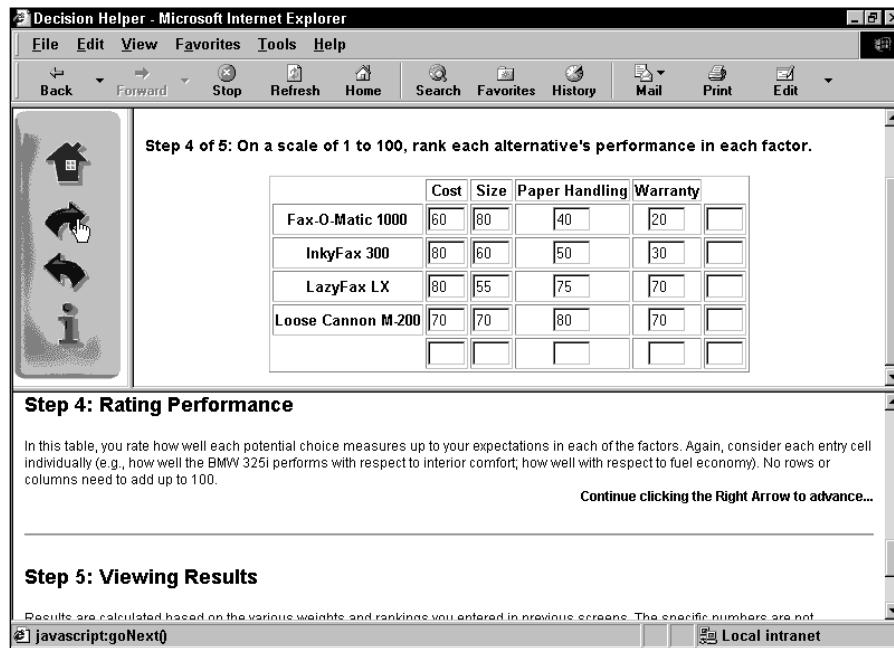

Figure 55-5: A massive table includes label data from earlier screen entries.

Functions for getting and setting performance data are complex because of the way I was forced to combine data into five “field” records. In other words, one parent cookie exists for each row of data cells in the table. To extract cell data for storage in the cookie, I use nested `for` loop constructions. The outer loop counts

the rows of the table, whereas the inner loop (with the *j* counter variable) works its way across the columns for each row.

Because all cells are named identically, they are indexed with values from 0 to 24. Calculating the row (*i * 5*) plus the column number establishes the cell index value. After you check for validity, each cell's value is added to the row's accumulated data. Each row is then saved to its corresponding cookie. As in the code for `dh3.htm`, the `return` statement is used as a way to break out of the function if an entry is deemed invalid.

Retrieving the data and populating the cells for the entire table requires an examination of each of the five performance cookies, and for each labeled cookie's data, a parsing for each period-delimited entry. After a given data point is in hand (one entry for a cell), it must go into the cell with the proper index.

```
<HTML>
<HEAD>
<TITLE>DH4</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!-- start
function getdh4Performance () {
    var oneRecord = ""
    for (var i = 0; i < 5; i++) {
        oneRecord = parent.getPerformance(i)
        if (oneRecord == null) {
            continue
        }
        for (var j = 0; j < 5; j++) {
            var recLen = oneRecord.length
            var offset = oneRecord.indexOf(".")
            var dataPoint = oneRecord.substring(0,offset)
            var cellNum = j + (i * 5)
            document.forms[0].ranking[cellNum].value = dataPoint
            oneRecord = oneRecord.substring(offset+1,recLen)
        }
    }
}
// end -->
</SCRIPT>
</HEAD>
function setdh4Performance () {
    for (var i = 0; i < 5; i++) {
        var oneRecord = ""
        for (var j = 0; j < 5; j++) {
            var cellNum = j + (i * 5)
            var dataPoint = document.forms[0].ranking[cellNum].value
            if (!parent.isValid(dataPoint)) {
                document.forms[0].ranking[cellNum].focus()
                document.forms[0].ranking[cellNum].select()
                return
            }
            oneRecord += dataPoint + "."
        }
        parent.setPerformance(i,oneRecord)
    }
    return
}
```

After the document is loaded, the `onLoad` event handler sends the document number to the parent global variable and brings focus to the first field of the table.

```
<BODY
onLoad=" parent.setTitleVar(4);document.forms[0].ranking[0].focus()"
<H2>The Decision Helper</H2>
<HR>
<H4>Step 4: On a scale of 1 to 100, rank each alternative's
performance in each factor.</H4>
<P><P>
```

To lessen the repetitive HTML for all tables, JavaScript again assembles and writes the HTML that defines the tables. In the first batch, the script uses yet another `for` loop to retrieve the factor entries from the parent cookie so that the words can be embedded into `<TH>` tags of the first row of the table. If every factor field is not filled in, the table cell is set to empty.

```
<SCRIPT LANGUAGE="JavaScript">
<!-- start
var output = "<CENTER><FORM NAME='perfRankings'><TABLE BORDER>"
output += "<TR><TD></TD><TD><TD>"
for (var i = 0; i < 5; i++) {
    var oneFactor = parent.getFactor(i)
    oneFactor = (oneFactor == null) ? "" : oneFactor
    output += "<TH>" + oneFactor + "</TH>"
}
output += "</TD>"
```

Next comes the assembly of subsequent rows of the table. The first column displays the name of each alternative (within `<TH>` tags). The remaining columns are text boxes, all with the same name and event handler. As each row of table definition is completed, it is written to the document. After the table and form closing tags are also written, the `getdh4Performance()` function retrieves all cookie data for the fields and distributes it accordingly.

```
for (var i = 0; i < 5; i++) {
    var oneAlt = parent.getAlternative(i)
    oneAlt = (oneAlt == null) ? "" : oneAlt
    output += "<TR><TD><TH>" + oneAlt + "</TH>"
    for (var j = 0; j < 5; j++) {
        output += "<TD ALIGN=CENTER><INPUT TYPE='text' SIZE=3 " +
            "NAME='ranking' VALUE='' onChange='setPerformance()'></TD>"
    }
    output += "</TR>"
    document.write(output)
    output = ""
}
document.write("</TABLE></FORM></CENTER>")
getdh4Performance ()
// end -->
</SCRIPT>
</BODY>
</HTML>
```

dh5.htm

From a math standpoint, dh5.htm's JavaScript gets pretty complicated. But because the complexity is attributed to the decision support calculations that turn the user's entries into results, I treat the calculation script shown here as a black box. You're free to examine the details, if you're so inclined.

Results appear in the form of a table (see Figure 55-6) with columns showing the numeric results and an optional graphical chart.

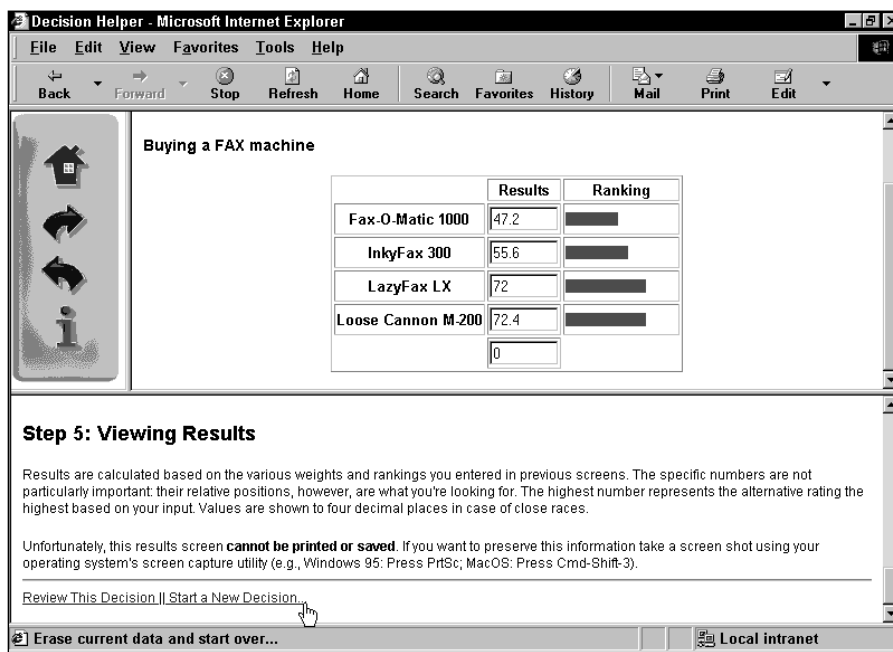

Figure 55-6: The results screen for a decision

For the purposes of this example, you only need to know a couple of things about the `calculate()` function. First, this function calls all the numeric data stored in parent cookies to fulfill values in its formulas. Second, results are tabulated and placed into a five-entry indexed array called `itemTotal[i]`. This array is defined as a global variable, so that its contents are available to scripts coming up in the Body portion of the document.

```
<HTML>
<HEAD>
<TITLE>DH5</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
<!-- start
var itemTotal = new Array()
function calculate() {
    var scratchpad = ""
    var importanceSum = 0
```

```

var oneRecord = parent.getImportance()
var weight = new Array()
for (var i = 0; i < 5; i++) {
    var recLen = oneRecord.length
    var offset = oneRecord.indexOf(".")
    scratchpad = oneRecord.substring(0,offset)
    importanceSum += (scratchpad == "" || scratchpad == "NaN") ?
        0 : parseInt(scratchpad)
    oneRecord = oneRecord.substring(offset+1,recLen)
}
oneRecord = parent.getImportance()
for (var i = 0; i < 5; i++) {
    recLen = oneRecord.length
    offset = oneRecord.indexOf(".")
    scratchpad = oneRecord.substring(0,offset)
    weight[i] = (scratchpad == "" && scratchpad == "NaN") ?
        0 : parseInt(scratchpad)/importanceSum * 100
    oneRecord = oneRecord.substring(offset+1,recLen)
}
for (var i = 0; i < 5; i++) {
    oneRecord = parent.getPerformance(i)
    if (oneRecord == null) {
        continue
    }
    scratchpad = 0
    for (var j = 0; j < 5; j++) {
        var recLen = oneRecord.length
        var offset = oneRecord.indexOf(".")
        var dataPoint = oneRecord.substring(0,offset)
        scratchpad += (dataPoint != "" || dataPoint == "NaN") ?
            parseInt(dataPoint) * weight[j] / 100 : 0
        oneRecord = oneRecord.substring(offset+1,recLen)
    }
    itemTotal[i] = scratchpad
}
}
calculate()
// end -->
</SCRIPT>
</HEAD>

```

Constructing this function served up many reminders about keeping data types straight. Because the data stored in cookies was in the form of strings, when it comes time to do some real math with those values, careful placement of the `parseInt()` function is essential for getting the math operators to work.

An `onLoad` event handler sends the document number to the global variable, as usual. The results display in this document relies heavily on stored and calculated values, so the table is constructed entirely out of JavaScript. That also means it can redisplay the decision name as part of the page.

```

<BODY onLoad="parent.setTitleVar(5)">
<H2>The Decision Helper</H2>
<HR>

```

```

<SCRIPT LANGUAGE="JavaScript">
<!-- start
document.write("<H4>" + parent.getDecisionName() + "</H4><P><P>")
var output = "<CENTER><FORM NAME='Results'><TABLE BORDER>"
output += "<TR><TD></TD><TD><TH>Results</TH><TH>Ranking</TH>"
output += "</TD>"

```

I need to break up the discussion of the `for` loop that produces the results because there are two distinct parts of this HTML assembly. The first, shown in the following script segment, assembles the first two cells of each row of the table. The first cell contains an embedded listing of the alternative name (in `<TH>` tags). To highlight the calculated values — and enable the `SIZE` attribute to do the artificial job of truncating the floating-point number — the results are shown in text boxes. For each row, the corresponding result in `itemTotal[i]` is inserted as the `VALUE` attribute of the text box. The `SIZE` attribute is set to 7, which allows the typical double-digit results, a decimal point, and four digits to the right of the decimal (an extra pixel shows on the Macintosh version, however).

```

for (var i = 0; i < 5; i++) {
  var oneAlt = parent.getAlternative(i)
  oneAlt = (oneAlt == null) ? "" : oneAlt
  itemTotal[i] = (oneAlt == "") ? 0 : itemTotal[i]
  output += "<TR><TD><TH>" + oneAlt + "</TH>"
  output += "<TD ALIGN=CENTER><INPUT TYPE='text' SIZE=7 " +
    "NAME='ranking' VALUE=" + itemTotal[i] + "></TD>"

```

For extra pizzazz, a third column “draws” a bar chart within a 100-pixel-wide cell. The bars are actually scalings of a one-pixel-wide `.gif` file (an orange line, 12 pixels tall). A single-color `.gif` image scales to fill whatever width is assigned in the `WIDTH` attribute. This method is faster and far better than a more tedious method (tedious from the Web page author’s point of view) of creating 100 different `.gif` files, one for each possible width of the bar. I also could have used a one-pixel square `.gif` file with equal ease.

```

  output += "<TD WIDTH=100>"
  chartWidth = Math.round(itemTotal[i])
  if (chartWidth > 0) {
    output += "<IMG SRC='chart.gif' HEIGHT=12 WIDTH=" +
      chartWidth + ">"
  }
  output += "</TD></TR>"
  document.write(output)
  output = ""
}
document.write("</TABLE></FORM></CENTER>")
// end -->
</SCRIPT>
</BODY>
</HTML>

```

dhHelp.htm

The only other code worth noting in this application is in the `dhHelp.htm` document, which appears in the lower-right frame of the window. At the end of this

document are two links that call separate JavaScript functions in this document's Head section. The Head functions are as follows:

```
<HEAD>
<TITLE>Decision Helper Help</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!--
function goFirst() {
    parent.entryForms.location = "dh1.htm"
    self.location.hash = "help1"
}
function restart() {
    if (confirm("Erase current decision and start a new one?")) {
        parent.initializeCookies()
        parent.entryForms.location = "dh1.htm"
        self.location.hash = "help1"
    }
}
// -->
</SCRIPT>
</HEAD>
```

One function merely returns the user to the beginning of the sequences for both the entry screens and the help screen. The second function is a rare instance in which a confirm dialog box makes sense: It is about to erase all entered data. If the user says it's okay to go ahead, the parent window's function for initializing all cookies is called, and the navigation for both the entry and help screens goes back to the beginning.

The links at the bottom of the document (see Figure 55-6) are coded to trigger JavaScript functions (rather than navigate to URLs) and include `onMouseOver` event handlers to provide more information about the link in the statusbar:

```
<A HREF="javascript:goFirst()" onMouseOver="window.status='Go back
to beginning to review data...';return true">Review This Decision
</A>||<A HREF="javascript:restart()"
onMouseOver="window.status='Erase current data and start over...';return true">
Start a New Decision... </A>
```

Further Thoughts

If you've managed to follow through with this application's discussions, you will agree that it's quite a JavaScript workout. But this application proves that, without a ton of code, JavaScript provides enough functionality to add a great deal of interactivity and pseudo-intelligence to an otherwise flat HTML document.

As an alternative to using cookies for data storage, I have also implemented a version of the application that uses text boxes defined in a frame defined with a row height of 0. This technique further challenges the synchronization of frames during reloading when a user resizes the browser window or navigates with the Back or Forward browser buttons. This alternate version is located on the CD-ROM for your own investigation and comparison.

Dynamic HTML also offers some possibilities for this application. The entire program can be presented in a no-frame window, with the navigation, interactive content, and instructions frames incorporated into individual positionable objects. The interactive content area can be treated almost like a slide show, with successive pages flying in from one edge.

Not only is this application instructive for many JavaScript techniques, but it is also fun to play with as a user. Some financial Web sites have adapted it to assist visitors with investment decisions. You can use it to dream about where to go on a dream vacation, or help you decide the most ethical of a few paths confronting you in a personal dilemma. There's something about putting in data, turning a crank, and watching results (with a bar chart to boot!) magically appear on the screen.

Application: Cross-Browser DHTML Map Puzzle

Dynamic HTML allows scripts to position, overlap, and hide or show elements under the control of style sheets and scripting. To demonstrate modern cross-browser DHTML development techniques, this chapter describes the details of a jigsaw puzzle game using pieces of a map of the “lower 48” United States (I think everyone would guess where Alaska and Hawaii go on a larger map of North America). I chose this application because it allows me to demonstrate several typical tasks you might want to script in DHTML: hiding and showing elements; handling events for multiple elements; tracking the position of an element with the mouse cursor; absolute positioning of elements; changing the z-order of elements; changing element colors; and animating movement of elements.

As with virtually any programming task, the example code here is not laid out as the quintessential way to accomplish a particular task. Each author brings his or her own scripting style, experience, and implementation ideas to a design. Very often, you have available several ways to accomplish the same end. If you find other strategies or tactics for the operations performed in these examples, it means you are gaining a good grasp of both JavaScript and Dynamic HTML.

The Puzzle Design

Figure 56-1 shows the finished map puzzle with the game in progress. To keep the code to a reasonable length, the example provides positionable state maps for only seven western states. Also, the overall design is intentionally Spartan so as to place more emphasis on the positionable elements and their scripting, rather than on fancy design.

CHAPTER

In This Chapter

Applying a DHTML API

Scripting, dragging, and layering of multiple elements

Event handling for three DOMs at once

Figure 56-1: The map puzzle game DHTML example (Images courtesy Map Resources—www.mapresources.com)

When the page initially loads, all the state maps are presented across the top of the puzzle area. The state labels all have a red background, and the silhouette of the continental United States has no features in it. To the right of the title is a question mark icon. A click of this icon causes a panel of instructions to glide to the center of the screen from the right edge of the browser window. That panel has a button that hides the panel.

To play the game (no scoring or time keeping is in this simplified version), a user clicks and drags a state with the goal of moving it into its rightful position on the silhouette. While the user drags the state, its label background to the right of the main map turns yellow to highlight the name of the state being worked on. To release the state in its trial position, the user releases the mouse button. If the state is within a four-pixel square region around its true location, the state snaps into its correct position and the corresponding label background color turns green. If the state is not dropped close enough to its destination, the label background reverts to red, meaning that the state still needs to be placed.

After the last state map is dropped into its proper place, all the label backgrounds will be green, and a congratulatory message is displayed where the state map pieces originally lay. Should a user then pick up a state and drop it out of position, the congratulatory message disappears.

I had hoped that all versions of the application would look the same on all platforms. They do, with one small exception. Because the labels are generated as positioned DIV elements for all browsers, NN4 (especially on the Windows version)

doesn't do as good a rendering job as other browsers. If I were to use genuine LAYER elements for the labels just for NN4, they'd look better. And, while the code could use scripts to generate LAYERS for NN4 and DIVs for others, the choice here was to stay with DIV elements alone. If you try this game on NN4 and other DHTML browsers, you will see minor differences in the way the labels are colored (red, yellow, and green) during game play. All other rendering and behavior is identical (although a rendering bug in NN6 is discussed later).

Implementation Details

Due to the number of different scripted properties being changed in this application, I decided to implement a lot of the cross-platform scripting as a custom API loaded from an external `.js` file library. The library, whose code is dissected and explained in Chapter 47, contains functions for most of the scriptable items you can access in DHTML. Having these functions available simplified what would have been more complex functions in the main part of the application.

Although I frown on using global variables except where absolutely necessary, I needed to assign a few globals for this application. All of them store information about the state map currently picked up by the user and the associated label. This information needs to survive the invocations of many functions between the time the state is picked up until it is dropped and checked against the "database" of state data.

That database is another global object — a global that I don't mind using at all. Constructed as a multidimensional array, each "record" in the database stores several fields about the state, including its destination coordinates inside the outline map and a Boolean field to store whether the state has been correctly placed in position.

Out of necessity for NN4, the state map images are encased in individual DIV elements. This makes their positionable characteristics more stable, as well as making it possible to capture mouse events that NN4's image objects do not recognize. If the application were being done only for IE4+ and W3C DOMs, the images themselves could be positionable, and the DHTML API could be used without modification.

The custom API

To begin the analysis of the code, you should be familiar with the API that is linked in from an external `.js` library file. Listing 47-2 contains that code and its description.

The main program

Code for the main program is shown in Listing 56-1. The listing is a long document, so I interlace commentary throughout the listing. Before diving into the code, however, allow me to present a preview of the structure of the document. With two exceptions (the map silhouette and the help panel), all positionable elements have their styles set via style sheets in the HEAD of the document. Notice the way class and id selectors are used to minimize the repetitive nature of the styles across so many similar items. After the style sheets come the scripts for the page. All of this

material is inside the <HEAD> tag section. I leave the <BODY> section to contain the visible content of the page. This approach is an organization style that works well for me, but you can adopt any style you like, provided various elements that support others on the page are loaded before the dependent items (for example, define a style before assigning its name to the corresponding content tag's ID attributes).

Listing 56-1: The Main Program (mapgame.htm)

```
<HTML>
<HEAD><TITLE>Map Game</TITLE>
```

Most of the positionable elements have their CSS properties established in the <STYLE> tag at the top of the document. Positionable elements whose styles are defined here include a text label for each state, a map for each state, and a congratulatory message. Notice that the names of the label and state map objects begin with a two-letter abbreviation of the state. This labeling comes in handy in the scripts when synchronizing the selected map and its label.

The label objects are nested inside the background map object. Therefore, the coordinates for the labels are relative to the coordinate system of the background map, not the page. That's why the first label has a `top` property of zero.

While both the background map and help panel are also positionable elements, scripts need to read the positions of these elements without first setting the values. Recall that in the IE4+ and W3C DOMs, the `style` property of an object does not reveal property values that are set in remote style sheet rules. While IE5 offers a `currentStyle` property to obtain the effective property attributes, neither IE4 nor the W3C DOM afford that luxury. Therefore, the style sheet rules for the background map and help panel are specified as `STYLE` attributes in those two elements' tags later in the listing.

```
<STYLE TYPE="text/css">
    .labels {position:absolute;
             background-color:red; layer-background-color:red;
             width:100; height:28; border:none; text-align:center}
    #azlabel {left:310; top:0}
    #calabel {left:310; top:29}
    #orlabel {left:310; top:58}
    #utlabel {left:310; top:87}
    #walabel {left:310; top:116}
    #nvlable {left:310; top:145}
    #idlabel {left:310; top:174}

    #camap {position:absolute; left:20; top:100; width:1;}
    #ormap {position:absolute; left:60; top:100; width:1;}
    #wamap {position:absolute; left:100; top:100; width:1;}
    #idmap {position:absolute; left:140; top:100; width:1;}
    #nvmap {position:absolute; left:180; top:100; width:1;}
    #azmap {position:absolute; left:220; top:100; width:1;}
    #utmap {position:absolute; left:260; top:100; width:1;}
```

```
#congrats {position:absolute; visibility:hidden; left:20; top:100; width:1;
color:red}
</STYLE>
```

The next statement loads the external `.js` library file that contains the API described in Chapter 47. I tend to load external library files before listing any other JavaScript code in the page, just in case the main page code relies on global variables or functions in its initializations.

```
<SCRIPT LANGUAGE="JavaScript" SRC="DHTMLapi.js"></SCRIPT>
```

Now comes the main script, which contains all the document-specific functions and global variables. Global variables here are ready to hold information about the selected state object (and associated details), as well as the offset between the position of a click inside a map object and the top-left corner of that map object. You will see that this offset is important to allow the map to track the cursor at the same offset position within the map. And because the tracking is done by repeated calls to a function (triggered by numerous mouse events), these offset values must have global scope.

```
// global declarations
var offsetX = 0
var offsetY = 0
var selectedObj
var states = new Array()
var statesIndexList = new Array()
var selectedStateLabel
```

As you will see later in the code, an `onLoad` event handler for the document invokes an initialization function, whose main job is to build the array of objects containing information about each state. The fields for each `state` object record are for the two-letter state abbreviation, the full name (not used in this application, but included for use in a future version), the `x` and `y` coordinates (within the coordinate system of the background map) for the exact position of the state, and a Boolean flag to be set to `true` whenever a user correctly places a state. I come back to the last two statements of the constructor function in a moment.

Getting the data for the `x` and `y` coordinates required some legwork during development. As soon as I had the pieces of art for each state and the code for dragging them around the screen, I disengaged the part of the script that tested for accuracy. Instead, I added a statement to the code that revealed the `x` and `y` position of the dragged item in the statusbar (rather than being bothered by alerts). When I carefully positioned a state in its destination, I copied the coordinates from the statusbar into the statement that created that state record. Sure, it was tedious, but after I had that info in the database, I could adjust the location of the background map and not have to worry about the destination coordinates, because they were based on the coordinate system inside the background map.

```
// object constructor for each state; preserves destination
// position; invokes assignEvents()
function state(abbrev, fullName, x, y) {
    this.abbrev = abbrev
    this.fullName = fullName
```

```

        this.x = x
        this.y = y
        this.done = false
        assignEvents(this)
        statesIndexList[statesIndexList.length] = abbrev
    }
    // initialize array of state objects
    function initArray() {
        states["ca"] = new state("ca", "California", 7, 54)
        states["or"] = new state("or", "Oregon", 7, 24)
        states["wa"] = new state("wa", "Washington", 23, 8)
        states["id"] = new state("id", "Idaho", 48, 17)
        states["az"] = new state("az", "Arizona", 45, 105)
        states["nv"] = new state("nv", "Nevada", 27, 61)
        states["ut"] = new state("ut", "Utah", 55, 69)
    }

```

The act of creating each state object causes all statements in the constructor function to execute. Moreover, they were executing within the context of the object being created. That opened up channels for two important processes in this application. One was to maintain a list of abbreviations as its own array. This becomes necessary later on when the script needs to loop through all objects in the `states` array to check their `done` properties. Because the array is set up like a hash table (with string index values), a `for` loop using numeric index values is out of the question. So, this extra `statesIndexList` array provides a numerically indexed array that can be used in a `for` loop; values of that array can then be used as index values of the `states` array. Yes, it's a bit of indirection, but other parts of the application benefit greatly by having the state information stored in a hash-table-like array.

One more act of creating each state object is the invocation of the `assignEvents()` function. Because each call to the constructor function bears a part of the name of a positionable map object (composed of the state's lowercase abbreviation and "map"), that value can be passed to the `assignEvents()` function, whose job is to assign event handlers to each of the map layers. While the actual assignment statements are the same for all supported browsers, assembling the references to the objects in each of the three DOM categories required object detection and associated syntax, very similar to the `getObject()` function of the API. In fact, if it weren't for the NN4-specific mechanism for turning on event capture, this function could have used `getObject()` from the library.

Here you can see the three primary user events that control state map dragging: Engage the map on `mousedown`; drag it on `mousemove`; release it on `mouseup`. These functions are described in a moment.

```

// assign event handlers to each map layer
function assignEvents(layer) {
    var obj
    if (document.layers) {
        obj = document.layers[layer.abbrev + "map"]
        obj.captureEvents(Event.MOUSEDOWN | Event.MOUSEMOVE | Event.MOUSEUP)
    } else if (document.all) {
        obj = document.all(layer.abbrev + "map")
    } else if (document.getElementById) {

```

```

        obj = document.getElementById(layer.abbrev + "map")
    }
    if (obj) {
        obj.onmousedown = engage
        obj.onmousemove = dragIt
        obj.onmouseup = release
    }
}

```

The `engage()` function invokes the following function, `setSelectedMap()`. It receives as its sole parameter an event object that is of the proper type for the browser currently running (that's done in the `engage()` function, described next). This function has three jobs to do, two of which set global variables. The first global variable, `selectedObj`, maintains a reference to the layer being dragged by the user. At the same time, the `selectedStateLabel` variable holds onto a reference to the layer that holds the label (recall that its color changes during dragging and release). All of this requires DOM-specific references that are generated through the aid of object detecting branches of the function. The last job of this function is to set the stacking order of the selected map to a value higher than the others so that while the user drags the map, it is in front of everything else on the page.

To assist in establishing references to the map and label layers, naming conventions of the HTML objects (shown later in the code) play an important role. Despite the event handlers being assigned to the DIVs that hold the images, the mouse events are actually targeted at the image objects. The code must associate some piece of information about the event target with the DIV that holds it ("parent" types of references don't work across all browsers, so we have to make the association the hard way). To prevent conflicts with so many objects on this page named with the lowercase abbreviations of the states, the image objects are assigned uppercase abbreviations of the state names. As `setSelectedMap()` begins to execute, it uses object detection to extract a reference to the element object regarded as the target of the event (`target` in NN4 and NN6, `srcElement` in IE). To make sure that the event being processed comes from an image, the next statement makes sure that the target has both `name` and `src` properties, in which case a lowercase version of the name is assigned to the `abbrev` local variable (if only IE4+ and W3C DOMs were in play here, a better verification is checking that the `tagName` property of the event target is `IMG`). That `abbrev` variable then becomes the basis for element names used in references to objects assigned to `selectedObj` and `selectedStateLabel`. Notice how the NN4 version requires a double-layer nesting to the reference for the label because labels are nested inside the `bgmap` layer.

The presence of a value assigned to `selectedObj` becomes an important case for all three drag-related functions later. That's why the `setSelectedMap()` function nulls out the value if the event comes from some other source.

```

/*****
BEGIN INTERACTION FUNCTIONS
*****/

```

```

// set global reference to map being engaged and dragged
function setSelectedMap(evt) {
    var target = (evt.target) ? evt.target : evt.srcElement
    var abbrev = (target.name && target.src) ?
        target.name.toLowerCase() : ""
    if (abbrev) {
        if (document.layers) {
            selectedObj = document.layers[abbrev + "map"]
            selectedStateLabel = document.layers["bgmap"].document.
                layers[abbrev + "label"]
        } else if (document.all) {
            selectedObj = document.all(abbrev + "map")
            selectedStateLabel = document.all(abbrev + "label")
        } else if (document.getElementById) {
            selectedObj = document.getElementById(abbrev + "map")
            selectedStateLabel = document.getElementById(abbrev + "label")
        }
        setZIndex(selectedObj, 100)
        return
    }
    selectedObj = null
    selectedStateLabel = null
    return
}

```

Next comes the `engage()` function definition. This function is invoked by `mousedown` events inside any of the state map layers. NN4 and NN6 pass an event object as the sole parameter to the function (picked up by the `evt` parameter variable). If that parameter contains a value, then it stands as the event object for the rest of the processing; but for IE, the `window.event` object is assigned to the `evt` variable. After setting the necessary object globals through `setSelectedMap()`, the next major task for `engage()` is to calculate and preserve in global variables the number of pixels within the state map layer at which the `mousedown` event occurred. By preserving these values, the `dragIt()` function makes sure that the motion of the state map layer keeps in sync with the mouse cursor at the very same point within the state map. If it weren't for taking the offset into account, the layer would jump unexpectedly to bring the top-left corner of the layer underneath the cursor. That's not how users expect to drag items on the screen.

The calculations for the offsets require a variety of DOM-specific properties. For example, both NN4 and NN6 offer `pageX` and `pageY` properties of the event object, but the coordinates of the layer itself require `left/top` properties for NN4 and `offsetLeft/offsetTop` properties for NN6. A nested object detection takes place in each assignment statement. The IE branch has some additional branching within each of the assignment statements. These extra branches cover a disparity in the way IE/Windows and IE/Mac report the offset properties of an event. IE/Windows ignores window scrolling, while IE/Mac takes scrolling into account. Later calculations for positioning must take window scrolling into account, so that scrolling is factored into the preserved offset global values if there are indications that the window has scrolled and the values are being affected by the scroll (in which case the offset values go very negative). The logic is confusing, and it won't make much sense until you see later how the positioning is invoked. Conceptually, all of these offset value calculations may seem like a can of worms, but they are essential, and are performed amazingly compactly.

After the offsets are established, the state's label layer's background color is set to yellow. The function ends with `return false` to make sure that the `mousedown` event doesn't propagate through the page (causing a contextual menu to appear on the Macintosh, for instance).

```
// set relevant globals onmousedown; set selected map
// object global; preserve offset of click within
// the map coordinates; set label color to yellow
function engage(evt) {
    evt = (evt) ? evt : event
    setSelectedMap(evt)
    if (selectedObj) {
        if (evt.pageX) {
            offsetX = evt.pageX - ((selectedObj.offsetLeft) ?
                selectedObj.offsetLeft : selectedObj.left)
            offsetY = evt.pageY - ((selectedObj.offsetTop) ?
                selectedObj.offsetTop : selectedObj.top)
        } else if (evt.offsetX || evt.offsetY) {
            offsetX = evt.offsetX - ((evt.offsetX < -2) ?
                0 : document.body.scrollLeft)
            offsetY = evt.offsetY - ((evt.offsetY < -2) ?
                0 : document.body.scrollTop)
        }
        setBGColor(selectedStateLabel,"yellow")
        return false
    }
}
```

The `dragIt()` function, compact as it is, provides the main action in the application by keeping a selected state object under the cursor as the user moves the mouse. This function is called repeatedly by the `mousemove` events, although the actual event handling methodology varies with platform (precisely the same way as with `engage()`, as shown previously). Regardless of the event property detected, event coordinates (minus the previously preserved offsets) are passed the `shiftTo()` function in the API.

Before the dragging action branch of the function ends, the event object's `cancelBubble` property is set to `true`. In truth, only the IE4+ and W3C DOM event objects have such a property, but assigning a value to a nonexistent object property for NN4 does no harm. It's important that this function operate as quickly as possible, because it must execute with each `mousemove` event. Canceling event bubbling helps in a way, but more important, the cancellation allows the `mousemove` event to be used for other purposes, as described in a moment.

```
// move DIV on mousemove
function dragIt(evt) {
    evt = (evt) ? evt : event
    if (selectedObj) {
        if (evt.pageX) {
            shiftTo(selectedObj, (evt.pageX - offsetX), (evt.pageY - offsetY))
        } else if (evt.clientX || evt.clientY) {
            shiftTo(selectedObj, (evt.clientX - offsetX), (evt.clientY -
offsetY))
        }
    }
}
```

```

    }
    evt.cancelBubble = true
    return false
  }
}

```

When a user drops the currently selected map object, the `release()` function invokes the `onTarget()` function to find out if the current location of the map is within range of the desired destination. If it is in range, the background color of the state label object is set to green, and the `done` property of the selected state's database entry is set to `true`. One additional test (the `isDone()` function call) looks to see if all the `done` properties are `true` in the database. If so, the `congrats` object is shown. But if the object is not in the right place, the label reverts to its original red color. In case the user moves a state that was previously okay, its database entry is also adjusted. No matter what the outcome, however, the user has dropped the map, so key global variables are set to `null` and the layer order for the item is set to zero (bottom of the heap) so that it doesn't interfere with the next selected map.

One more condition is possible in the `release()` function. As shown later in the initialization function, the `document` object's `onmousemove` event handler is assigned to the `release()` function (to compare the `onmousemove` events for the state maps go to `dragIt()`). The reasoning behind this document-level event assignment is that no matter how streamlined the dragging function may be, it is possible for the user to move the mouse so fast that the map can't keep up. At that point, `mousemove` events are firing at the `document` (or other object, eventually bubbling up to the `document`), and not the state map. If that happens while a state map is registered as the selected object, but the image is no longer the target of the event, the code performs the same act as if the user had released the map. The label reverts to red, and all relevant globals are set to `null`, preventing any further interaction with the map until the user mouses down again on the map.

```

// onmouseup, see if dragged map is near its destination
// coordinates; if so, mark it as 'done' and color label green
function release(evt) {
  evt = (evt) ? evt : event
  var target = (evt.target) ? evt.target : evt.srcElement
  var abbrev = (target.name && target.src) ?
    target.name.toLowerCase() : ""
  if (abbrev && selectedObj) {
    if (onTarget(evt)) {
      setBGColor(selectedStateLabel, "green")
      states[abbrev].done = true
      if (isDone()) {
        show("congrats")
      }
    } else {
      setBGColor(selectedStateLabel, "red")
      states[abbrev].done = false
      hide("congrats")
    }
  }
}

```

```

        setZIndex(selectedObj, 0)
    } else if (selectedStateLabel) {
        setBGColor(selectedStateLabel, "red")
    }
    selectedObj = null
    selectedStateLabel = null
}

```

To find out if a dropped map is in (or near) its correct position, the `onTarget()` function first calculates the target spot on the page by adding the location of the `bgmap` object to the coordinate positions stored in the `states` database. Because the `bgmap` object doesn't come into play in other parts of this script, it is convenient to pass merely the object name to the two API functions that get the object's left and top coordinate points.

Next, the script uses platform-specific properties to get the recently dropped state map object's current location. A large `if` condition checks whether the state map object's coordinate point is within a four-pixel square region around the target point. If you want to make the game easier, you can increase the cushion values from 2 to 3 or 4.

If the map is within the range, the script calls the `shiftTo()` API function to snap the map into the exact destination position and reports back to the `release()` function the appropriate Boolean value.

```

// compare position of dragged element against the destination
// coordinates stored in corresponding state object; after shifting
// element to actual destination, return true if item is within
// 2 pixels.
function onTarget(evt) {
    evt = (evt) ? evt : event
    var target = (evt.target) ? evt.target : evt.srcElement
    var abbrev = (target.name && target.src) ?
        target.name.toLowerCase() : ""
    if (abbrev && selectedObj) {
        var x = states[abbrev].x + getObjectLeft("bgmap")
        var y = states[abbrev].y + getObjectTop("bgmap")
        var objX, objY
        if (selectedObj.pageX) {
            objX = selectedObj.pageX
            objY = selectedObj.pageY
        } else if (selectedObj.style) {
            objX = parseInt(selectedObj.style.left)
            objY = parseInt(selectedObj.style.top)
        }
        if ((objX >= x-2 && objX <= x+2) &&
            (objY >= y-2 && objY <= y+2)) {
            shiftTo(selectedObj, x, y)
            return true
        }
        return false
    }
    return false
}

```

A for loop cycles through the states database (with the help of the hash table values stored indirectly in the `statesIndexList` array) to see if all of the `done` properties are set to `true`. When they are, the `release()` function (which calls the `isDone()` function) displays the congratulatory object. Do note that NN6.0 may exhibit rendering difficulties when hiding and showing the `congrats` object. This problem should be fixed in a subsequent release of the browser.

```
// test whether all state objects are marked 'done'
function isDone() {
    for (var i = 0; i < statesIndexList.length; i++) {
        if (!states[statesIndexList[i]].done) {
            return false
        }
    }
    return true
}
```

The help panel is created differently than the map and label objects (details coming up in a moment). When the user clicks the Help button at the top of the page, the instructions panel flies in from the right edge of the window (see Figure 56-2). The `showHelp()` function begins the process by setting its location to the current right window edge, bringing its layer to the very front of the heap, showing the object. To assist `moveHelp()` in calculating the center position on the screen, the `showHelp()` function retrieves (just once per showing) the DOM-specific property for the width of the help panel. That value is passed as a parameter to `moveHelp()` as it is repeatedly invoked through the `setInterval()` mechanism.

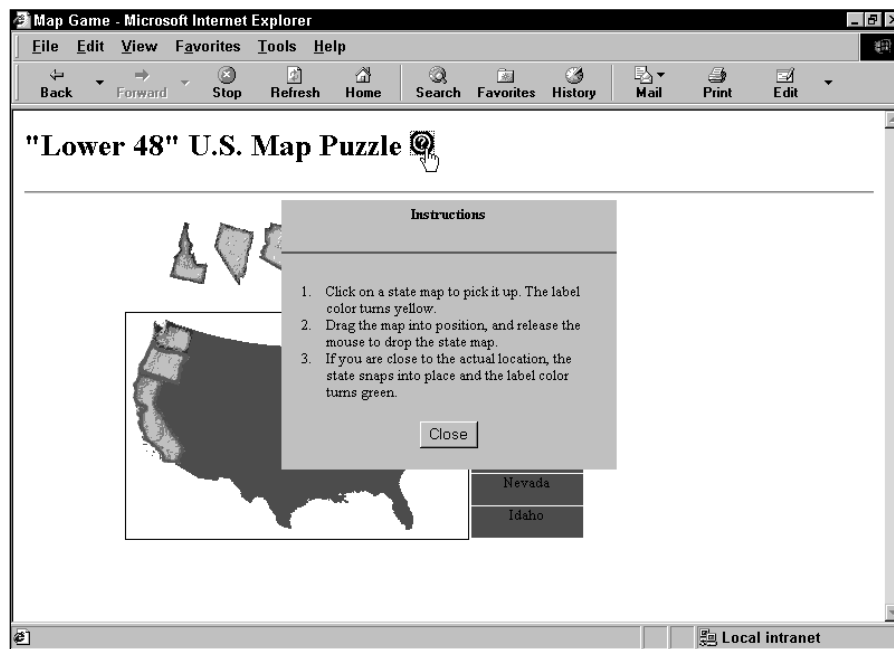

Figure 56-2: Instructions panel “flies” in from left to center screen.

```

/*****
BEGIN HELP ELEMENT FUNCTIONS
*****/
// initiate show action
function showHelp() {
    var objName = "help"
    var helpWidth = 0
    shiftTo(objName, insideWindowWidth, 80)
    setZIndex(objName,1000)
    show(objName)
    if (document.layers) {
        helpWidth = document.layers[objName].document.width
    } else if (document.all) {
        helpWidth = document.all(objName).offsetWidth
    } else if (document.getElementById) {
        if (document.getElementById(objName).offsetWidth >= 0) {
            helpWidth = document.getElementById(objName).offsetWidth
        }
    }
    intervalID = setInterval("moveHelp(" + helpWidth + ")", 1)
}

```

In the `moveHelp()` function, the help object is shifted in five-pixel increments to the left. The ultimate destination is the spot where the object is in the middle of the browser window. That midpoint must be calculated each time the page loads, because the window may have been resized. The width of the help object, received as a parameter to the function, gets a workout in the mid-point calculation.

This function is called repeatedly under the control of a `setInterval()` method in `showHelp()`. But when the object reaches the middle of the browser window, the interval ID is canceled, which stops the animation.

The help object processes a mouse event to hide the object. An extra `clearInterval()` method is called here in case the user clicks the object's Close button before the object has reached mid-window (where `moveHelp()` cancels the interval). The script also shifts the position to the right edge of the window, but it isn't absolutely necessary, because the `showHelp()` method positions the window there.

```

// iterative move help DIV to center of window
function moveHelp(w) {
    shiftBy("help",-5,0)
    var objectLeft = getObjectLeft("help")
    if (objectLeft <= (insideWindowWidth/2) - w/2) {
        clearInterval(intervalID)
    }
}
// hide the help DIV
function hideMe() {
    clearInterval(intervalID)
    hide("help")
    shiftTo("help", insideWindowWidth, 80)
}

```

The document's `onLoad` event handler invokes the `init()` function, which, in turn, calls two functions and assigns the document object's `onmousemove` event handler. The first is `initArray()`, which builds the `states[]` database and assigns event handlers to the state map layers. Because the layers are defined so late in the document, initializing their events after the page has loaded is safest.

For convenience in moving the help window to the center of the browser window, the `setWinWidth()` function sets a global variable (`insideWindowWidth`) to hold the width of the browser window. This function is also invoked by the `onResize` event handler for the window to keep the value up to date.

```
// calculate center of window for help DIV
function setWinWidth() {
    if (window.innerWidth) {
        insideWindowWidth = window.innerWidth
    } else if (document.body.scrollWidth) {
        insideWindowWidth = document.body.scrollWidth
    } else if (document.width) {
        insideWindowWidth = document.width
    }
}

/*****
INITIALIZE THE APPLICATION
*****/
// initialize application
function init() {
    initArray()
    setWinWidth()
    document.onmousemove = release
}
</SCRIPT>
</HEAD>
```

Now comes the part of the document that generates the visible content. The `<BODY>` tag contains the two event handlers just discussed. An image rollover for the help icon simply displays a message in the statusbar.

```
<BODY onLoad="init()" onResize="setWinWidth()">
<H1>"Lower 48" U.S. Map Puzzle <A HREF="javascript:void showHelp()"
onMouseOver="status='Show help panel...';return true"
onMouseOut="status='';return true"><IMG SRC="info.gif" HEIGHT=22 WIDTH=22
BORDER=0></A></H1>
<HR>
```

Next come tags for all of the DIV elements. The `STYLE` attribute for the `bgmap` DIV lets scripts read the positioned values to assist in calculating positions in the `onTarget()` function, as shown previously. The `bgmap` layer also contains all labels so that if the design calls for moving the map to another part of the page, the labels follow automatically. Notice how the lowercase state abbreviations are part of the names of both the label and map layers. As you saw in a few functions shown previously, a systematic approach to object naming can offer powerful shortcuts in determining references to elements.

```

<DIV ID=bgmap STYLE="position:absolute; left:100; top:180; width:406"><IMG
SRC="us11.gif" WIDTH=306 HEIGHT=202 BORDER=1>&nbsp;</IMG>
<DIV CLASS="labels" ID=azlabel>Arizona</DIV>
<DIV CLASS="labels" ID=calabel>California</DIV>
<DIV CLASS="labels" ID=orlabel>Oregon</DIV>
<DIV CLASS="labels" ID=utlabel>Utah</DIV>
<DIV CLASS="labels" ID=walabel>Washington</DIV>
<DIV CLASS="labels" ID=nvlabel>Nevada</DIV>
<DIV CLASS="labels" ID=idlabel>Idaho</DIV>
</DIV>

<DIV ID=camap><IMG NAME="CA" SRC="ca.gif" WIDTH=47 HEIGHT=82 BORDER=0></DIV>
<DIV ID=ormap><IMG NAME="OR" SRC="or.gif" WIDTH=57 HEIGHT=45 BORDER=0></DIV>
<DIV ID=wamap><IMG NAME="WA" SRC="wa.gif" WIDTH=38 HEIGHT=29 BORDER=0></DIV>
<DIV ID=idmap><IMG NAME="ID" SRC="id.gif" WIDTH=34 HEIGHT=55 BORDER=0></DIV>
<DIV ID=azmap><IMG NAME="AZ" SRC="az.gif" WIDTH=38 HEIGHT=45 BORDER=0></DIV>
<DIV ID=nvmap><IMG NAME="NV" SRC="nv.gif" WIDTH=35 HEIGHT=56 BORDER=0></DIV>
<DIV ID=utmap><IMG NAME="UT" SRC="ut.gif" WIDTH=33 HEIGHT=41 BORDER=0></DIV>

<DIV ID=congrats><H1>Congratulations!</H1></DIV>

```

In developing this application, I encountered an unfriendly NN4 bug. When defining the help panel as a positioned DIV element in NN4, the browser exhibited unwanted behavior after the instruction panel was shown and flown into place under script control. Even after hiding the help layer, the page no longer received mouse events, making it impossible to pick up a state map after the instructions appeared. The problem did not surface, however, if the help object was defined in the document with a `<LAYER>` tag.

Therefore, I did what I don't like to do unless absolutely necessary: I created branches in the content that used `document.write()` to create the same content with different HTML syntax, depending on the browser. For non-LAYER browsers, the page creates the same kind of block (with the `<DIV>` tag pair) used elsewhere in the document. Positioning properties are assigned to this block via a `STYLE` attribute in the `<DIV>` tag. You cannot assign a style in the `<STYLE>` tag that is visible to the entire document, because that specification and a like-named `<LAYER>` tag get confused.

For NN4, the page uses the `<LAYER>` tag and loads the content of the object from a separate HTML file (`instrux.htm`). One advantage I had with the `<LAYER>` tag was that I could assign an initial horizontal position of the help object with a JavaScript entity. The entity reaches into the `window.innerWidth` property to set the `LEFT` attribute of the layer.

```

<SCRIPT LANGUAGE="JavaScript">
var output = ""
if (document.layers) {
    output = "<LAYER ID='help' TOP=80 LEFT=&{window.innerWidth}; WIDTH=300
VISIBILITY='HIDDEN' SRC='instrux.htm'></LAYER>"
} else {
    output = "<DIV ID='help' onClick='hideMe()' STYLE='position:absolute;
visibility:hidden; top:80; width:300; border:none; background-
color:#98FB98;'>\n"

```

```

    output += "<P STYLE='margin-
top:5'><CENTER><B>Instructions</B></CENTER></P>\n"
    output += "<HR COLOR='seagreen'\n<OL STYLE='margin-right:20'>"
    output += "<LI>Click on a state map to pick it up. The label color turns
yellow.\n"
    output += "<LI>Drag the map into position, and release the mouse to drop the
state map.\n"
    output += "<LI>If you are close to the actual location, the state snaps into
place and the label color turns green.\n"
    output += "</OL>\n<FORM>\n<CENTER><INPUT TYPE='button'
VALUE='Close'\n</FORM></DIV>"
}
document.write(output)
</SCRIPT>
</BODY>
</HTML>

```

This page has a lot of code to digest in one reading. Run the application, study the structure of the source code listing file, and re-read the previous explanations. It may take several readings for a mental picture of the application to form.

Lessons Learned

As soon as the external cross-platform API was in place, it helped frame a lot of the other code in the main program. The APIs provided great comfort in that they encouraged me to reference a complex object fully in the main code as a platform-shared value (for example, the `selectedObj` and `selectedStateLabel` global variables). At the same time, I could reference top-level elements (that is, non-nested objects) simply by their names when passing them to API functions.

In many respects, the harder task was defining the style sheet attributes and syntax that both browsers would treat similarly. In the case of the label objects, I couldn't reach complete parity in a cross-platform environment (the labels look different in NN4), and in the case of the `help` object, I had to code the HTML separately for each platform. Therefore, when approaching this kind of project, work first with the HTML and CSS syntax to build the look that works best for all platforms. Then start connecting the scripted wires. You may have to adjust the CSS code if you find odd behavior in one platform or the other with your scripting, but starting with a good layout is still easier.

But without a doubt the biggest lesson you learn from working on a project like this is how important it is to test an application on as many browsers and operating systems as possible. Designing a cross-platform application on one browser and having it run flawlessly on the other the first time is nearly impossible. Be prepared to go back and forth among multiple browsers, breaking and repairing existing working code along the way until you eventually reach a version that works on every browser that you can test.

Application: Transforming XML Data Islands

Chapter 52 ends with an example of an interactive outliner whose data arrives in XML format. The data is embedded in an HTML document inside an XML data island, which is thus far supported only on the Windows versions of IE5 and later. The application described in this chapter picks up from there.

As you recall from the Chapter 52 outline, the node structure of the XML data was used as a guide to the structure for a one-time rendering of HTML elements. There was a one-to-one correlation between XML element nesting and the HTML element nesting. Adjusting style sheet properties for displaying or hiding elements controlled all interactivity. What you're about to see here is a case for converting XML into JavaScript objects that can be used multiple times as a convenient data source for HTML that is displayed in any number of formats. In particular, you see how JavaScript's array sorting prowess supplies XML-supplied data with extraordinary flexibility in presentation.

You will see a lot of code in this chapter. The code is presented here as a way to demonstrate the potential for rich data handling. At the same time, the code may provide ideas for server-side processing of XML data being output to the client. If a server program can convert the XML data into the shortcut object and array notation of Version 4 browsers or later, suddenly a broader range of browsers is capable of dealing with data stored as XML on the server.

CHAPTER

In This Chapter

Designing XML data islands

Complex JavaScript data structures

Advanced array sorting

Dynamic tables

Application Overview

Understanding the data is a good place to start in describing this application. The scenario is a small American company (despite its grandiose name: GiantCo) that has divided the country into three sales regions. Two of the regions have two sales representatives, while the third region has three reps. The time is at the end of a fiscal year, at which point the management wants to review and present the performance of each salesperson. An XML report delivers the sales forecast and actual sales per quarter for each sales rep. A single HTML and JavaScript page (with the XML data embedded as a data island inside an IE <XML> tag) is charged with not only displaying the raw tabular data, but also allowing for a variety of views and sorting possibilities so that management can analyze performance by sales rep and region, as well as by quarter.

A server-based searching and reporting program collects the requested data and outputs each sales rep's record in an XML structure, such as the following one:

```
<SALESREP>
  <EMPLOYEEID>12345</EMPLOYEEID>
  <CONTACTINFO>
    <FIRSTNAME>Brenda</FIRSTNAME>
    <LASTNAME>Smith</LASTNAME>
    <EMAIL>brendas@giantco.com</EMAIL>
    <PHONE>312-555-9923</PHONE>
    <FAX>312-555-9901</FAX>
  </CONTACTINFO>
  <MANAGER>
    <EMPLOYEEID>02934</EMPLOYEEID>
    <FIRSTNAME>Alistair</FIRSTNAME>
    <LASTNAME>Renfield</LASTNAME>
  </MANAGER>
  <REGION>Central</REGION>
  <SALESRECORD>
    <PERIOD>
      <ID>Q1_2000</ID>
      <FORECAST>300000</FORECAST>
      <ACTUAL>316050</ACTUAL>
    </PERIOD>
    <PERIOD>
      <ID>Q2_2000</ID>
      <FORECAST>280000</FORECAST>
      <ACTUAL>285922</ACTUAL>
    </PERIOD>
    <PERIOD>
      <ID>Q3_2000</ID>
      <FORECAST>423000</FORECAST>
      <ACTUAL>432930</ACTUAL>
    </PERIOD>
    <PERIOD>
      <ID>Q4_2000</ID>
      <FORECAST>390000</FORECAST>
      <ACTUAL>399200</ACTUAL>
    </PERIOD>
  </SALESRECORD>
</SALESREP>
```

As you can see, the data consists of several larger blocks, such as contact information, a pointer to the rep's manager, and then the details of each quarterly period's forecast and actual sales. The goal is to present the data in table form with a structure similarly shown in Figure 57-1. Not only is the raw data presented, but numerous calculations are also made on the results, such as the percentage of quota attained for each reporting period, plus totals along each axis of the spreadsheet-like table.

Sales Rep	Q1 2000		Q2 2000		Q3 2000		Q4 2000		Total 2000	
	Fest/Act	Quota	Fest/Act	Quota	Fest/Act	Quota	Fest/Act	Quota	Fest/Act	Quota
Laura Almerson	145000 155090	106.9%	170000 189000	111.1%	205000 255030	124.4%	275000 268600	97.6%	795000 867720	109.1%
Jonathan Ames	270000 256050	94.8%	290000 295922	102%	305000 304030	99.6%	375000 382300	101.9%	1240000 1238302	99.8%
Stephen Borneo	255000 276050	108.2%	270000 225922	83.6%	305000 314030	102.9%	335000 354600	105.8%	1165000 1170602	100.4%
Esmerelda Hernandez	209000 210920	100.9%	195000 199200	102.1%	205000 235030	114.6%	255000 263700	103.4%	864000 908850	105.1%
Russell Kim	245000 241090	98.4%	245000 247800	101.1%	266000 277030	104.1%	255000 289000	113.3%	1011000 1054920	104.3%
Michael McCartney	285000 295800	103.7%	265000 298700	112.7%	315000 334030	106%	325000 348500	107.2%	1190000 1277030	107.3%
Brenda Smith	300000 316050	105.3%	280000 285922	102.1%	423000 432930	102.3%	390000 399200	102.3%	1393000 1434102	102.9%
Grand Total	1709000 1751050	102.4%	1715000 1742466	101.6%	2024000 2152110	106.3%	2210000 2305900	104.3%	7658000 7951526	103.8%

Figure 57-1: One view of the XML data output

Just above the table are two SELECT elements. These controls' labels indicate that the table's data can be sorted by a number of criteria and the results of each sort can be ordered in different ways. Sorting in the example offers the following possibilities:

Representative's Name
 Sales Region
 Q1 Forecast
 Q1 Actual
 Q1 Performance
 [the last three also for Q2, Q3, Q4]
 Total Forecast
 Total Actual
 Total Performance

Ordering of the sorted results is a choice between "Low to High" or "High to Low." While ordering of most sort categories is obviously based on numeric value, the sorting of the representatives' names is based on the alphabetical order of the last names. One other point about the user interface is that the design needs to signify via table cell background color the sales region of each representative. The

colors aren't easily distinguishable in Figure 57-1, but if you open the actual example listing in IE5+/Windows on your computer, you will see the coloration.

Implementation Plan

Clearly all the data needed for numerous sorted and ordered views arrives in one batch in the XML island. Despite the element and node referencing properties and methods of the W3C DOM, trying to use the XML elements as the sole data store for scripts to sort the data each time would be impractical. For one thing, none of the elements have ID attributes — there's no need for it in the XML stored on the server database. And even if they did have IDs, how would scripts that you desire to write for generalizability make use of them unless the IDs were generated in a well-known sequence? Moreover, after a sales rep's record is rendered in the table, how easy would it be to dive back into that record and drill down for further information, such as the name of a representative's manager?

A solution that can empower the page author in this case is to use the node-walking properties and methods of the W3C DOM to assemble a JavaScript-structured database while the page loads. In other words, the conversion is performed just once during page loading, and the JavaScript version is preserved in an array (of XML "records" in this case) as a global variable. Any transformations on the data can be done from the JavaScript database with the help of additional powers of the language.

Given that route, the basic operation of the scripting of the page is schematically simple:

1. Convert the XML into an array of objects at load time.
2. Predefine all necessary sorting functions based on properties of those objects.
3. Provide a function that rebuilds the HTML table each time data is sorted.

With this sequence in mind, now look into the code that does the job.

The Code

Rather than work through the long document in source code order, the following descriptions follow a more functional order. You can open the actual source code file to see where the various functions are positioned. To best understand this application, seeing the "how" rather than the "where" is more important. Also, many of the code lines (even some single expressions) are too wide for the printed page and therefore break unnaturally in the listings that follow. Trust the formatting of the source file on the CD-ROM.

Style sheets

For the example provided on the CD-ROM, one set of style sheet rules is embedded in the HTML document. As you can see from the rule selectors, many are tied to very specific classes of table-related elements used to render the content. In a

production version of this application, I would expect that there would be more and quite different views of the data available to the users, such as bar charts for each salesperson or region. Each view would likely require its own unique set of style sheet rules. In such a scenario, the proper implementation would be to use the LINK element to bring in a different external style sheet file for each view type. All could be linked in at the outset, but only the current `styleSheet` object would be enabled.

```
<STYLE TYPE="text/css">
XML {display:none}
TD {text-align:right}
TD.rep, TD.grandTotalLabel {text-align:center}
TR.East {background-color:#FFFFCC}
TR.Central {background-color:#CCFFFF}
TR.West {background-color:#FFCCCC}
TR.QTotal {background-color:#FFFF00}
TD.repTotal {background-color:#FFFF00}
TD.grandTotal {background-color:#00FF00}
H1 {font-family:"Comic Sans MS",Helvetica,sans-serif}
</STYLE>
```

One style sheet rule is essential: The one that suppresses the rendering of any XML element. That data is hidden from the user's view.

Initialization sequence

An `onLoad` event handler invokes the `init()` function, which sets a lot of machinery in motion to get the document ready for user interaction. Its most important job is running a `for` loop that builds the JavaScript database from the XML elements. Next, it sorts the database based on the current choice in the sorting SELECT element. The sorting function ends by triggering the rendering of the table. These three actions correspond to the fundamental operation of the entire application.

```
// initialize global variable that stores JavaScript data
var db = new Array()

// Initialization called by onLoad
function init() {
    for (var i = 0;
        i <
document.getElementById("reports").getElementsByTagName("SALESREP").length;
        i++) {
            db[db.length] = getOneSalesRep(i)
        }
    selectSort(document.getElementById("sortChooser"))
}
```

Converting the data

The controlling factor for creating the JavaScript database is the structure of the XML data island. As you may recall, the elements inside the XML data island can be accessed only through a reference to the XML container. The ID of that element in

this application is reports. Data for each sales rep is contained by a SALESREP element. The number of SALESREP elements determines how many records (JavaScript objects) are to be added to the db array. A call to the `getOneSalesRep()` function creates an object for each sales representative's data.

Despite the length of the `getOneSalesRep()` function, its operation is very straightforward. Most of the statements do nothing more than retrieve the data inside the various XML elements within a SALESREP container and assign that data to a like-named property of the custom object. Following the structure of the XML example shown earlier in this chapter, you can see where some properties of a JavaScript object representing the data are, themselves, objects or arrays. For example, one of the properties is called `manager`, corresponding to the MANAGER element. But that element has nested items inside. Then, making those nested elements properties of a `manager` object is only natural. Similarly, the repetitive nature of the data within each of the four quarterly periods calls for even greater nesting: The object property named `sales` is an array, with each item of the array corresponding to one of the periods. Each period also has three properties (a period ID, forecast sales, and actual sales). Thus, the `sales` property is an array of objects.

```
function getOneSalesRep(i) {
    // create new, empty object
    var oneRecord = new Object()
    // get a shortcut reference to one SALESREP element
    var oneElem =
document.getElementById("reports").getElementsByName("SALESREP")[i]
    // start assigning element data to oneRecord object properties
    oneRecord.id =
oneElem.getElementsByTagName("EMPLOYEEID")[0].firstChild.data
    var contactInfoElem =
oneElem.getElementsByTagName("CONTACTINFO")[0]
    oneRecord.firstName =
contactInfoElem.getElementsByTagName("FIRSTNAME")[0].firstChild.data
    oneRecord.lastName =
contactInfoElem.getElementsByTagName("LASTNAME")[0].firstChild.data
    oneRecord.eMail =
contactInfoElem.getElementsByTagName("EMAIL")[0].firstChild.data
    oneRecord.phone =
contactInfoElem.getElementsByTagName("PHONE")[0].firstChild.data
    oneRecord.fax =
contactInfoElem.getElementsByTagName("FAX")[0].firstChild.data
    // make the manager property its own object
    oneRecord.manager = new Object()

    // get a shortcut reference to the MANAGER element
    var oneMgrElem = oneElem.getElementsByTagName("MANAGER")[0]
    // start assigning element data to manager object properties
    oneRecord.manager.id =
oneMgrElem.getElementsByTagName("EMPLOYEEID")[0].firstChild.data
    oneRecord.manager.firstName =
oneMgrElem.getElementsByTagName("FIRSTNAME")[0].firstChild.data
    oneRecord.manager.lastName =
oneMgrElem.getElementsByTagName("LASTNAME")[0].firstChild.data
    oneRecord.region =
```

```

oneElem.getElementsByTagName("REGION")[0].firstChild.data

    // make the sales property a new array
    oneRecord.sales = new Array()
    // get a shortcut reference to the collection of
    // periods in the SALESRECORD element
    var allPeriods =
oneElem.getElementsByTagName("SALESRECORD")[0].childNodes
var temp
var accumForecast = 0, accumActual = 0
// loop through periods
for (var i = 0; i < allPeriods.length; i++) {
    if (allPeriods[i].nodeType == 1) {
        // make new object for a period's data
        temp = new Object()
        // start assigning period data to the new object
        temp.period =
allPeriods[i].getElementsByTagName("ID")[0].firstChild.data
        temp.forecast =
parseInt(allPeriods[i].getElementsByTagName("FORECAST")[0].firstChild.data)
        temp.actual =
parseInt(allPeriods[i].getElementsByTagName("ACTUAL")[0].firstChild.data)
        // run analysis on two properties and preserve result
        temp.quotaPct = getPercentage(temp.actual, temp.forecast)
        oneRecord.sales[temp.period] = temp
        // accumulate totals for later
        accumForecast += temp.forecast
        accumActual += temp.actual
    }
}
// preserve accumulated totals as oneRecord properties
oneRecord.totalForecast = accumForecast
oneRecord.totalActual = accumActual
// run analysis on accumulated totals
oneRecord.totalQuotaPct = getPercentage(accumActual, accumForecast)
// hand back the stuffed object to be put into the db array
return oneRecord
}
// calculate percentage of actual/forecast
function getPercentage(actual, forecast) {
    var pct = (actual/forecast * 100) + ""
    pct = pct.match(/\d*\.\d/)
    return parseFloat(pct)
}

```

Assuming that the raw XML database stores only the sales forecast and actual dollar figures, it is up to analysis programs to perform their own calculations, such as how the actual sales compare against the forecasts. As you saw in the illustration of the rendered table, this application not only displays the percentage differences between the pairs of values, but it also provides sorting facilities on those percentages. To speed the sorting, the percentages are calculated as the JavaScript database is being accumulated, and the percentages are stored as properties of each object. Percentage calculation is called upon in two different statements of the

`getOneSalesRep()` function, so that the calculation is broken out to its own function, `getPercentage()`. In that function, the two passed values are massaged to calculate the percentage value, and then the string result is formatted to no more than one digit to the right of the decimal (by way of a regular expression). The value returned for the property assignment is converted to a number data type, because sorting on these values needs to be done according to numeric sorting, rather than string sorting.

You can already get a glimpse at the contribution JavaScript is making to the scripted representation of the data transmitted in XML form. By virtue of planning for subsequent calculations, the JavaScript object contains considerably more information than was originally delivered, yet all the properties are derived from “hard” data supplied by the server database.

Sorting the JavaScript database

With so many sorting keys for the user to choose from, it’s no surprise that sorting code occupies a good number of script lines in this application. All sorting code consists of two major blocks: *dispatching* and *sorting*.

The dispatching portion is nothing more than one gigantic `switch` construction that sends execution to one of the seventeen (!) sorting functions that match whichever sort key is chosen in the `SELECT` element on the page. This dispatcher function, `selectSort()`, is also invoked from the `init()` function at load time. Thus, if the user makes a choice in the page, navigates to another page, and then returns with the page still showing the previous selection, the `onLoad` event handler will reconstruct the table precisely as it was. When sorting is completed, the table is drawn, as you see shortly.

```
// begin sorting routines
function selectSort(chooser) {
    switch (chooser.value) {
        case "byRep" :
            db.sort(sortDBByRep)
            break
        case "byRegion" :
            db.sort(sortDBByRegion)
            break
        case "byQ1Fcst" :
            db.sort(sortDBByQ1Fcst)
            break
        case "byQ1Actual" :
            db.sort(sortDBByQ1Actual)
            break
        case "byQ1Quota" :
            db.sort(sortDBByQ1Quota)
            break
        case "byQ2Fcst" :
            db.sort(sortDBByQ2Fcst)
            break
        case "byQ2Actual" :
            db.sort(sortDBByQ2Actual)
            break
    }
}
```

```

    case "byQ2Quota" :
        db.sort(sortDBByQ2Quota)
        break
    case "byQ3Fcst" :
        db.sort(sortDBByQ3Fcst)
        break
    case "byQ3Actual" :
        db.sort(sortDBByQ3Actual)
        break
    case "byQ3Quota" :
        db.sort(sortDBByQ3Quota)
        break
    case "byQ4Fcst" :
        db.sort(sortDBByQ4Fcst)
        break
    case "byQ4Actual" :
        db.sort(sortDBByQ4Actual)
        break
    case "byQ4Quota" :
        db.sort(sortDBByQ4Quota)
        break
    case "byTotalFcst" :
        db.sort(sortDBByTotalFcst)
        break
    case "byTotalActual" :
        db.sort(sortDBByTotalActual)
        break
    case "byTotalQuota" :
        db.sort(sortDBByTotalQuota)
        break
    }
    drawTextTable()
}

```

Each specific sorting routine is a function that automatically works repeatedly on pairs of entries of an array (see Chapter 37). Array entries here (from the `db` array) are objects—and rather complex objects at that. The benefit of using JavaScript array sorting is that the sorting can be performed on any property of objects stored in the array. For example, sorting on the `lastName` property of each `db` array object is based on a comparison of the `lastName` property for each of the pairs of array entries passed to the `sortDBByRep()` sort function. But looking down a little further, you can see that the mechanism allows sorting on even more deeply nested properties, such as the `sales.Q1_2000.forecast` property of each array entry. If a property in an object can be referenced, it can be used as a sorting property inside one of these functions.

```

function sortDBByRep(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.lastName < b.lastName) ? -1 : 1
    } else {
        return (a.lastName > b.lastName) ? -1 : 1
    }
}

```

```
function sortDBByRegion(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.region < b.region) ? -1 : 1
    } else {
        return (a.region > b.region) ? -1 : 1
    }
}
function sortDBByQ1Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q1_2000.forecast - b.sales.Q1_2000.forecast)
    } else {
        return (b.sales.Q1_2000.forecast - a.sales.Q1_2000.forecast)
    }
}
function sortDBByQ1Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q1_2000.actual - b.sales.Q1_2000.actual)
    } else {
        return (b.sales.Q1_2000.actual - a.sales.Q1_2000.actual)
    }
}
function sortDBByQ1Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q1_2000.quotaPct - b.sales.Q1_2000.quotaPct)
    } else {
        return (b.sales.Q1_2000.quotaPct - a.sales.Q1_2000.quotaPct)
    }
}
function sortDBByQ2Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q2_2000.forecast - b.sales.Q2_2000.forecast)
    } else {
        return (b.sales.Q2_2000.forecast - a.sales.Q2_2000.forecast)
    }
}
function sortDBByQ2Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q2_2000.actual - b.sales.Q2_2000.actual)
    } else {
        return (b.sales.Q2_2000.actual - a.sales.Q2_2000.actual)
    }
}
function sortDBByQ2Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q2_2000.quotaPct - b.sales.Q2_2000.quotaPct)
    } else {
        return (b.sales.Q2_2000.quotaPct - a.sales.Q2_2000.quotaPct)
    }
}
function sortDBByQ3Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q3_2000.forecast - b.sales.Q3_2000.forecast)
    }
}
```

```
    } else {
        return (b.sales.Q3_2000.forecast - a.sales.Q3_2000.forecast)
    }
}
function sortDBByQ3Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q3_2000.actual - b.sales.Q3_2000.actual)
    } else {
        return (b.sales.Q3_2000.actual - a.sales.Q3_2000.actual)
    }
}
function sortDBByQ3Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q3_2000.quotaPct - b.sales.Q3_2000.quotaPct)
    } else {
        return (b.sales.Q3_2000.quotaPct - a.sales.Q3_2000.quotaPct)
    }
}
function sortDBByQ4Fcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q4_2000.forecast - b.sales.Q4_2000.forecast)
    } else {
        return (b.sales.Q4_2000.forecast - a.sales.Q4_2000.forecast)
    }
}
function sortDBByQ4Actual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q4_2000.actual - b.sales.Q4_2000.actual)
    } else {
        return (b.sales.Q4_2000.actual - a.sales.Q4_2000.actual)
    }
}
function sortDBByQ4Quota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.sales.Q4_2000.quotaPct - b.sales.Q4_2000.quotaPct)
    } else {
        return (b.sales.Q4_2000.quotaPct - a.sales.Q4_2000.quotaPct)
    }
}
function sortDBByTotalFcst(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.totalForecast - b.totalForecast)
    } else {
        return (b.totalForecast - a.totalForecast)
    }
}
function sortDBByTotalActual(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.totalActual - b.totalActual)
    } else {
        return (b.totalActual - a.totalActual)
    }
}
}
```

```
function sortDBByTotalQuota(a, b) {
    if (document.getElementById("orderChooser").value == "inc") {
        return (a.totalQuotaPct - b.totalQuotaPct)
    } else {
        return (b.totalQuotaPct - a.totalQuotaPct)
    }
}
```

For this application, all sorting functions branch in their execution based on the choice made in the “Ordered” SELECT element on the page. The relative position of the two array elements under test in these simple subtraction comparison statements reverses when the sort order is from low to high (increasing) and when it is from high to low (decreasing). This kind of array sorting is extremely powerful in JavaScript and probably escapes the attention of most scripters.

Constructing the table

As recommended back in Chapter 27’s discussion of TABLE and related elements, it is best to manipulate the structure of a TABLE element by way of the specialized methods for tables, rather than mess with nodes and elements. The `drawTextTable()` function is devoted to employing those methods to create the rendered contents of the table below the headers (which are hard-wired in the document’s HTML). Composing an eleven-column table requires a bit of code, and the `drawTextTable()`’s length attests to that fact. You can tell by just glancing at the code, however, that for big chunks of it, there is a comfortable regularity that is aided by the JavaScript object that holds the data.

Additional calculations take place while the table’s elements are being added to the TABLE element. Column totals are accumulated during the table assembly (row totals are calculated as the object is generated and preserved as properties of the object). A large `for` loop cycles through each (sorted) row of the `db` array; each row of the `db` array corresponds to a row of the table. Class names are assigned to various rows or cells so that they will pick up the style sheet rules defined earlier in the document. Another subtlety of this version is that the `region` property of a sales rep is assigned to the `title` property of a row. If the user pauses the mouse pointer anywhere in that row, the name of the region pops up briefly.

```
function drawTextTable() {
    var newRow
    var accumQ1F = 0, accumQ1A = 0, accumQ2F = 0, accumQ2A = 0
    var accumQ3F = 0, accumQ3A = 0, accumQ4F = 0, accumQ4A = 0
    deleteRows(document.getElementById("mainTableBody"))
    for (var i = 0; i < db.length; i++) {
        newRow = document.getElementById("mainTableBody").insertRow(i)
        newRow.className = db[i].region
        newRow.title = db[i].region + " Region"
        appendCell(newRow, "rep", db[i].firstName + " " + db[i].lastName)
        appendCell(newRow, "Q1", db[i].sales.Q1_2000.forecast + "<BR>" +
            db[i].sales.Q1_2000.actual)
        appendCell(newRow, "Q1", db[i].sales.Q1_2000.quotaPct + "%")
        appendCell(newRow, "Q2", db[i].sales.Q2_2000.forecast + "<BR>" +
            db[i].sales.Q2_2000.actual)
    }
}
```

```

        appendCell(newRow, "Q2", db[i].sales.Q2_2000.quotaPct + "%")
        appendCell(newRow, "Q3", db[i].sales.Q3_2000.forecast + "<BR>" +
            db[i].sales.Q3_2000.actual)
        appendCell(newRow, "Q3", db[i].sales.Q3_2000.quotaPct + "%")
        appendCell(newRow, "Q4", db[i].sales.Q4_2000.forecast + "<BR>" +
            db[i].sales.Q4_2000.actual)
        appendCell(newRow, "Q4", db[i].sales.Q4_2000.quotaPct + "%")
        accumQ1F += db[i].sales.Q1_2000.forecast
        accumQ1A += db[i].sales.Q1_2000.actual
        accumQ2F += db[i].sales.Q2_2000.forecast
        accumQ2A += db[i].sales.Q2_2000.actual
        accumQ3F += db[i].sales.Q3_2000.forecast
        accumQ3A += db[i].sales.Q3_2000.actual
        accumQ4F += db[i].sales.Q4_2000.forecast
        accumQ4A += db[i].sales.Q4_2000.actual
        appendCell(newRow, "repTotal", db[i].totalForecast + "<BR>" +
            db[i].totalActual)
        appendCell(newRow, "repTotal", db[i].totalQuotaPct + "%")
    }
    newRow = document.getElementById("mainTableBody").insertRow(i)
    newRow.className = "QTotal"
    newRow.title = "Totals"
    appendCell(newRow, "grandTotalLabel", "Grand Total")
    appendCell(newRow, "Q1", accumQ1F + "<BR>" + accumQ1A)
    appendCell(newRow, "Q1", getPercentage(accumQ1A, accumQ1F) + "%")
    appendCell(newRow, "Q2", accumQ2F + "<BR>" + accumQ2A)
    appendCell(newRow, "Q2", getPercentage(accumQ2A, accumQ2F) + "%")
    appendCell(newRow, "Q3", accumQ3F + "<BR>" + accumQ3A)
    appendCell(newRow, "Q3", getPercentage(accumQ3A, accumQ3F) + "%")
    appendCell(newRow, "Q4", accumQ4F + "<BR>" + accumQ4A)
    appendCell(newRow, "Q4", getPercentage(accumQ4A, accumQ4F) + "%")
    var grandTotalFcst = accumQ1F + accumQ2F + accumQ3F + accumQ4F
    var grandTotalActual = accumQ1A + accumQ2A + accumQ3A + accumQ4A
    appendCell(newRow, "grandTotal", grandTotalFcst + "<BR>" + grandTotalActual)
    appendCell(newRow, "grandTotal",
        getPercentage(grandTotalActual, grandTotalFcst) + "%")
}
// insert a cell and its content to a recently added row
function appendCell(Trow, Cclass, txt) {
    var newCell = Trow.insertCell(Trow.cells.length)
    newCell.className = Cclass
    newCell.innerHTML = txt
}
// clear previous table content if there is any
function deleteRows(tbl) {
    while (tbl.rows.length > 0) {
        tbl.deleteRow(0)
    }
}
}

```

Many standalone statements at the end of the `drawTextTable()` function are devoted exclusively to generating the Grand Total row, in which the accumulated column totals are entered. At the same time, the `getPercentage()` function,

described earlier, is invoked several times again to derive the quota percentage for the accumulated grand total values in each quarter as well as the complete year.

SELECT controls

To round out the code listing for this application, the values assigned to the two SELECT elements obviously have a lot to do with the execution of numerous functions in this application. Nothing magic takes place here, but you can see the extent of the detail required in assigning script-meaningful hidden values, and human-meaningful text for both SELECT elements. For example, dividing lines help organize the long sort key list into three logical blocks.

```
<P>Sort by: <SELECT ID="sortChooser" onChange="selectSort(this)">
  <OPTION VALUE="byRep">Representative
  <OPTION VALUE="byRegion">Sales Region
  <OPTION VALUE="">-----
  <OPTION VALUE="byQ1Fcst">Q1 Forecast
  <OPTION VALUE="byQ1Actual">Q1 Actual
  <OPTION VALUE="byQ1Quota">Q1 Performance
  <OPTION VALUE="byQ2Fcst">Q2 Forecast
  <OPTION VALUE="byQ2Actual">Q2 Actual
  <OPTION VALUE="byQ2Quota">Q2 Performance
  <OPTION VALUE="byQ3Fcst">Q3 Forecast
  <OPTION VALUE="byQ3Actual">Q3 Actual
  <OPTION VALUE="byQ3Quota">Q3 Performance
  <OPTION VALUE="byQ4Fcst">Q4 Forecast
  <OPTION VALUE="byQ4Actual">Q4 Actual
  <OPTION VALUE="byQ4Quota">Q4 Performance
  <OPTION VALUE="">-----
  <OPTION VALUE="byTotalFcst">Total Forecast
  <OPTION VALUE="byTotalActual">Total Actual
  <OPTION VALUE="byTotalQuota">Total Performance
</SELECT>
 
Ordered: <SELECT ID="orderChooser" onChange="selectOrder()">
  <OPTION VALUE="inc">Low to High
  <OPTION VALUE="dec">High to Low
</SELECT>
</P>
```

Dreams of Other Views

Confining the example to just one type of view — a table of numbers — should help you grasp the important processes taking place. But with the XML data converted to JavaScript objects, you can build many other views of the same data into the same page. For example, a script could completely hide the numeric table, and generate a different one that draws bar charts for each sales representative or each region (see Chapter 55 for a scripted bar chart example). The horizontal axis would be the four quarters, and the vertical axis would be dollars or quota percentages. Clicking a bar opens a small window or layer to reveal more detail from the sales representative's record, such as the name of the person's manager. More SELECT

elements can let the user select any combination of subsets of the data in either bar chart or numeric table form to facilitate visual comparisons. You might be even more creative and devise ways of showing the data by way of overlapping positioned elements.

The point is that despite the kinds of rendering opportunities afforded by the XSL Transform mechanism (even if you can get comfortable in the syntax and mental model it presents to authors), JavaScript's detailed access to the DOM offers far more potential. Eventually plenty of content authors will mix the two technologies by embedding JavaScript into XSL style sheets to supplement XSL features.

What About NN6?

Microsoft's XML data islands are not (yet anyway) part of the W3C DOM. As NN6 was being readied for release, there was little imperative to implement this feature in the browser (very few convenience features of the IE4+ DOM were adopted in NN6). And, as mentioned elsewhere, without the XML data islands, combining XML and HTML in the same document is not strictly "legal." Oddly enough, the example in this chapter works in NN6, but it is an accident. For one thing, the tag names in the XML data do not overlap with any HTML tag names. But don't take this to mean you can get away with these kinds of constructions. Even if you can force fit your XML into an HTML document to get it to work, you have no guarantee it will work in subsequent browser versions.

To combine the powers of JavaScript and the W3C DOM to operate on XML data in NN6, we have to keep our eyes on availability of the browser's built-in capabilities for standard XSL Transform facilities. Some of it works even in the earliest releases of the new browser, but what works in NN6 doesn't work (or work well) in IE5+, and vice versa. Veteran scripters, who bear scars from battles with DOM incompatibilities, may choose to delay deployments of such content until there is more unanimity among the latest browsers. Browser incompatibilities are responsible for a massive inflation of object model vocabulary (not to mention the thickness of this book). Perhaps the day will come when the code we write for even complex applications will run cleanly on a broad range of installed browsers on a broad range of devices. Don't give up on the dream.

JavaScript and Browser Object Quick Reference

The following pages contain reduced printouts of a handy pamphlet whose Adobe Acrobat (.pdf) file you can find on the companion CD-ROM. I modified the arrangement of the following material for printing in this appendix. The .pdf files on the CD-ROM, which you can print for quick reference, contain all of the pages you see in this appendix.

This compact guide enables you to see at a glance the breadth of each object's properties, methods, and event handlers. The core JavaScript language section applies to all scriptable browsers. The document object model, however, is divided into the three basic model types that developers must support:

- ◆ Fully compatible with all browsers
- ◆ Internet Explorer proprietary object model
- ◆ W3C DOM-compatible browsers

As a measure of how much the language — and especially the object models — have grown in recent times, the same quick reference for the previous edition of this book amounted to four printable sides. This edition requires no fewer than 12 sides.

The large vocabularies and divisive nature of the existing object models (complicated ever further in the IE browser due to operating system incompatibilities) create a major challenge in designing a portable, quick reference like the one shown on the following pages. Object model groupings in the Quick Reference are designed to be as consistent as possible across the three models; so if you attempt to build applications for multiple object models, you can find, say, the document object's property listings in similar positions in each of the three model references. Development for the IE4+ and W3C DOM environments still requires knowledge about the original object model because that legacy model persists in current practice.

To conserve space in the IE4+ and W3C DOM sections, I do not list all HTML element objects (even though I cover them in chapters of this book). A large percentage of HTML elements share the same properties, methods, and event handlers — all of which are listed in each object model’s section (in a box labeled “All HTML Elements”). For example, the DIV element has a specific role and behavior from the point of view of the HTML rendering engine; however, as a scriptable object, it has no properties, methods, or event handlers beyond the ones it shares with all HTML elements. Therefore, the only HTML elements that I list within the IE4+ and W3C DOM sections are those that have one or more properties, methods, and event handlers that are either unique to that object or are shared by only a few related elements. Once you are acquainted with the items in common with all elements, it is easier to find the items that are special to a listed object.

If you choose to print the Acrobat files, first read the CD-ROM file `Choose a Version.txt` to determine the format you’d like to print. Then read the `howtoprt.txt` file in the folder dedicated to your chosen format. This file contains printing and assembly directions for optimum convenience with respect to the format you choose.

toLocaleLowerCase() N6, IE5.5
toLocaleUpperCase() N6, IE5.5
toLowerCase()
toString() N4, IE4
toUpperCase() N4, IE4
valueOf() N4, IE4

```

(1) Most of the static String object.
(2) Added behavior in N4 includes ability to accept a regex parameter; second parameter (limit integer) to limit the number of splits to be included; a space string parameter signifying any white space character.

38

Regular Expressions^{N4, IE4}

```

global
compile(regex)
ignoreCase
input(1), IE5.5
test("string") (2)
lastIndex
multiline(1), IE5.5
lastMatch(1), IE5.5
lastParen(1), IE5.5
leftContext(1), IE5.5
rightContext(1)
prototype
source
$1...$9

```

(1) Property of the static RegExp object.
(2) Returns an array with properties: index, input, [0], [1], ..., [n].

35

Boolean^{N3, J2}

```

JavaScript and Browser Objects Quick Reference

Appendix A

JavaScript Bible, 4th Edition by Danny Goodman

How to Use This Quick Reference

This guide contains quick reference info for the core JavaScript language, the original document object model (2 pp), the IE4+DHTML object model (4 pp), and the W3C DOM object model (4 pp) as implemented in IE5+ and NN6. All uppercase object names refer to HTML elements (IE4+ and W3C DOMs). The three columns in each box list the object's properties, methods, and event handlers in that order. Read the compatibility guides for each section.

Numbers in the upper left corners of object squares are chapter numbers in which the object is covered in detail.

Basic browser and operating system notation codes are as follows:
 N — Netscape Navigator IE — MS Internet Explorer
 W — Win32 OS M — Macintosh OS

See the accompanying file for printing and collating instructions in booklet or broadside configurations.

Original DOM Compatibility Guide

Baseline browsers for this section are NN2, IE3/1, and IE 3.01/Mac. An item with no notation is compatible back to that level. Notations indicate the browser and version in which the property, method, or event handler was introduced. An item showing to be introduced only in IE, for example, does not exist for any NN version.

Except for the window and navigator objects (whose listings cover all browsers and versions), new features listed in this section cover only through NN4 (and IE4 when they matched a new NN4 feature). Notations are as follows:

- N3 — New in NN3
 - N4 — New in NN4
 - J2 — New in IE3, JScript.dll ver.2
 - IE4 — New in IE4, all OSes
 - (S) — Requires signed scripts (NN)
- Additional window and navigator object notations are:
- W4 — IE4+/Windows only
 - W5 — IE5+/Windows only
 - IE5.5 — IE5.5+ all OSes
 - M4 — IE4+/Mac only
 - M5 — IE5+/Mac only
 - N6 — New in NN6

Except for items marked *N4*, Only (which are not carried over into NN6), an item listed for an early browser is also available in the IE4+ and/or W3C DOM object models. '(None)' means that no methods or events exist for the current object through IE3 and NN4.

IE4+ DHTML DOM Compatibility Guide

The baseline browser for this section is MSIE 4. An item with no notation is compatible back to that level for all OS versions. Notations as follows:
 W4 — IE4+/Windows only
 W5 — IE5+/Windows only
 IE5 — IE5+ all OSes
 IE5.5 — IE5.5+ (only Win tested)
 M5 — IE5+/Mac
 All HTML element objects share items from "All HTML" box on Page 1. "None" means no special methods or events for the current object.

JavaScript Reserved Words

Every programming language has a built-in vocabulary of keywords that you cannot use for the names of variables and the like. Because a JavaScript function is an object that uses the function name as an identifier for the object, you cannot employ reserved words for function names either. Netscape's list of reserved words closely echoes that of the Java language; thus, many of the keywords in the list do not—at least yet—apply to JavaScript. Remember that JavaScript keywords are case-sensitive. While you may get away with using these words in other cases, it may lead to unnecessary confusion for someone reading your scripts.

Answers to Tutorial Exercises

This appendix provides answers to the tutorial exercises that appear in Part II of this book (Chapters 4 through 12).

Chapter 4 Answers

1. The music jukebox (a) and temperature calculator (d) are good client-side JavaScript applications. Even though the jukebox relies on server storage of the music files, you can create a more engaging and responsive user interface of buttons, swappable images, and information from a plug-in, such as LiveAudio, Windows Media Player, or QuickTime. The temperature calculator is a natural, because all processing is done instantaneously on the client, rather than having to access the server for each conversion.

The Web site visit counter (b) that accumulates the number of different visitors to a Web site is a server-side CGI application, because the count must be updated and maintained on the server. At best, a client-side counter could keep track of the number of visits the user has made to a site and report to the user how many times he or she has been to the site. The storage requires scripting the cookie (Chapter 16). A chat room application (c) done properly requires server facilities to open up communication channels among all users connected simultaneously. Client-side scripting by itself cannot create a live chat environment.

2. The first task is to determine a valid identifier for the General Motors location in the hierarchy. Then “connect the dots”:
 - a. General_Motors.Chevrolet.Malibu
 - b. General_Motors.Pontiac.Firebird
 - c. General_Motors.Pontiac.Bonneville

3.
 - a. Valid, because it is one contiguous word. InterCap spelling is fine.
 - b. Valid, because an underscore character is acceptable between words.
 - c. Not valid, because an identifier cannot begin with a numeral.
 - d. Not valid, because no spaces are allowed.
 - e. Not valid, because apostrophes and most other punctuation are not allowed.
4. The names that I assign here are arbitrary, but the paths are not.

```
document.myLink
document.entryForm
document.entryForm.nameField
document.entryForm.addressField
document.entryForm.phoneField
document.entryForm.noArchiveBox
```

5. `<INPUT TYPE="button" NAME="Hi" VALUE="Howdy" onClick="alert('Hello to you, too!')">`

Chapter 5 Answers

1.

```
<SCRIPT LANGUAGE="JavaScript">
  <!--
  document.write("Hello, world.")
  // -->
</SCRIPT>
```
2.

```
<HTML>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
  <!--
  document.write("Hello, world.")
  // -->
</SCRIPT>
</BODY>
</HTML>
```

3.

```
<HTML>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
<!--
// write a welcome message to the world
document.write("Hello, world.")
// -->
</SCRIPT>
</BODY>
</HTML>
```
4. My answer is written so that both event handlers call separate functions. You can also have each event handler invoke the `alert()` method inline.
- ```
<HTML>
<HEAD>
<TITLE>An onLoad= script</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!--
function done() {
 alert("The page has finished loading.")
}
function alertUser() {
 alert("Ouch!")
}
// -->
</SCRIPT>
</HEAD>
<BODY onLoad="done()">
Here is some body text.
<FORM>
 <INPUT TYPE="button" NAME="oneButton" VALUE="Press Me!"
onClick="alertUser()">
</FORM>
</BODY>
</HTML>
```
5. a. The page displays two text fields.
- b. The user enters text into the first field and either clicks or tabs out of the field to trigger the `onChange` event handler.
- c. The function displays an all-uppercase version of one field into the other.

## Chapter 6 Answers

1. a. Valid.
- b. Not valid. The variable needs to be a single word, such as `howMany` or `how_many`.
- c. Valid.
- d. Not valid. The variable name cannot begin with a numeral. If the variable needs a number to help distinguish it from other similar variables, then put the numeral at the end: `address1`.

2.
  - a. 4
  - b. 40
  - c. "4020"
  - d. "Robert"
3. The functions are `parseInt()` and `parseFloat()`. Strings to be converted are passed as parameters to the functions:  
`parseInt(document.forms[0].entry.value)`.
4. Both text field values are strings that must be converted to numbers before they can be arithmetically added together. You can use the `parseFloat()` functions either on the variable assignment expressions (for example, `var value1 = parseFloat(document.adder.inputA.value)`) or in the addition expression (`document.adder.output.value = parseFloat(value1) + parseFloat(value2)`).
5. Concatenate means to join together two strings to become one string.

## Chapter 7 Answers

1. Because the references in the function point to a text field named `entry` inside a form named `entryForm`, be sure to assign those names to the `NAME` attributes in the respective HTML tags.

stateEntered[27] = 1867
stateEntered[28] = 1864
stateEntered[29] = 1788
stateEntered[30] = 1787
stateEntered[31] = 1912
stateEntered[32] = 1788
stateEntered[33] = 1789
stateEntered[34] = 1889
stateEntered[35] = 1803
stateEntered[36] = 1907
stateEntered[37] = 1859
stateEntered[38] = 1787
stateEntered[39] = 1790
stateEntered[40] = 1788
stateEntered[41] = 1889
stateEntered[42] = 1796
stateEntered[43] = 1845
stateEntered[44] = 1896
stateEntered[45] = 1791
stateEntered[46] = 1788
stateEntered[47] = 1889
stateEntered[48] = 1863
stateEntered[49] = 1848
stateEntered[50] = 1890

function getStateDate() {
 var selectedState = document.entryForm.entry.value
 for (var i = 0; i < USStates.length; i++) {
 if (USStates[i] == selectedState) {
 break
 }
 }
 alert("That state entered the Union in " +
stateEntered[i] + ".")
}
</SCRIPT>
</HEAD>
<BODY>
<FORM NAME="entryForm">
Enter the name of a state:
<INPUT TYPE="text" NAME="entry">
<INPUT TYPE="button" VALUE="Look Up Entry Date"
onClick="getStateDate()">
</FORM>
</BODY>
</HTML>

```

2. Several problems plague this function definition. Parentheses are missing from the first `if` construction's condition statement. Curly braces are missing from the second nested `if...else` construction. A mismatch of curly braces also exists for the entire function. The following is the correct form (changes and additions in boldface):

```

function format(ohmage) {
 var result
 if (ohmage >= 10e6) {
 ohmage = ohmage / 10e5
 }
}

```

```

 result = ohmage + " Mohms"
 } else {
 if (ohmage >= 10e3) {
 ohmage = ohmage / 10e2
 result = ohmage + " Kohms"
 } else {
 result = ohmage + " ohms"
 }
 }
 alert(result)
}

```

**3. Here is one possibility:**

```

for (var i = 1; i < tomatoes.length; i++) {
 if (tomatoes[i].looks == "mighty tasty") {
 break
 }
}
var myTomato = tomatoes[i]

```

**4. The new version defines a different local variable name for the dog.**

```

<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
var aBoy = "Charlie Brown" // global
var hisDog = "Snoopy" // global
function sampleFunction() {
 // using improper design to demonstrate a point
 var WallacesDog = "Gromit" // local version of hisDog
 var output = WallacesDog + " does not belong to " +
 aBoy + ".
"
 document.write(output)
}
</SCRIPT>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
sampleFunction() // runs as document loads
document.write(hisDog + " belongs to " + aBoy + ".")
</SCRIPT>
</BODY>
</HTML>

```

**5. The application uses three parallel arrays and is structured very much like the solution to question 1. Learn to reuse code whenever you can.**

```

<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
var planets = new Array(4)
planets[0] = "Mercury"
planets[1] = "Venus"
planets[2] = "Earth"
planets[3] = "Mars"

```

```

var distance = new Array(4)
distance[0] = "36 million miles"
distance[1] = "67 million miles"
distance[2] = "93 million miles"
distance[3] = "141 million miles"

var diameter = new Array(4)
diameter[0] = "3100 miles"
diameter[1] = "7700 miles"
diameter[2] = "7920 miles"
diameter[3] = "4200 miles"

function getPlanetData() {
 var selectedPlanet = document.entryForm.entry.value
 for (var i = 0; i < planets.length; i++) {
 if (planets[i] == selectedPlanet) {
 break
 }
 }
 var msg = planets[i] + " is " + distance[i]
 msg += " from the Sun and "
 msg += diameter[i] + " in diameter."
 document.entryForm.output.value = msg
}
</SCRIPT>
</HEAD>
<BODY>
<FORM NAME="entryForm">
Enter the name of a planet:
<INPUT TYPE="text" NAME="entry">
<INPUT TYPE="button" VALUE="Look Up a Planet"
onClick="getPlanetData()">

<INPUT TYPE="text" SIZE=70 NAME="output">
</BODY>
</HTML>

```

## Chapter 8 Answers

1.
  - a. Close, but no cigar. Array references are always plural:  
`window.document.forms[0].`
  - b. Not valid: `self` refers to a window and `entryForm` must refer to a form. Where's the document? It should be `self.document.entryForm.entryField.value.`
  - c. Valid.
  - d. Not valid. The document reference is missing from this one.
  - e. Valid, assuming that `newWindow` is a variable holding a reference to a subwindow.
2. `window.status = "Welcome to my Web page."`

3. `document.write("<H1>Welcome to my Web page.</H1>")`

4. A script in the Body portion invokes a function that returns the text entered in a `prompt()` dialog box.

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function askName() {
 var name = prompt("What is your name, please?","")
 return name
}
</SCRIPT>
</HEAD>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
document.write("Welcome to my web page, " + askName() + ".")
</SCRIPT>
</BODY>
</HTML>
```

5. The URL can be derived from the `href` property of the `location` object.

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function showLocation() {
 alert("This page is at: " + location.href)
}
</SCRIPT>
</HEAD>
<BODY onLoad="showLocation()">
Blah, blah, blah.
</BODY>
</HTML>
```

## Chapter 9 Answers

1. For Listing 9-1, pass the text object because that's the only object involved in the entire transaction.

```
<HTML>
<HEAD>
<TITLE>Text Object value Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function upperMe(field) {
 field.value = field.value.toUpperCase()
}
</SCRIPT>
</HEAD>
<BODY>
<FORM onSubmit="return false">
```

```

<INPUT TYPE="text" NAME="convertor" VALUE="sample"
onChange="upperMe(this)">
</FORM>
</BODY>
</HTML>

```

**For Listing 9-2, the button invokes a function that communicates with a different element in the form. Pass the form object.**

```

<HTML>
<HEAD>
<TITLE>Checkbox Inspector</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function inspectBox(form) {
 if (form.checkThis.checked) {
 alert("The box is checked.")
 } else {
 alert("The box is not checked at the moment.")
 }
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
<INPUT TYPE="checkbox" NAME="checkThis">Check here

<INPUT TYPE="button" VALUE="Inspect Box"
onClick="inspectBox(this.form)">
</FORM>
</BODY>
</HTML>

```

**For Listing 9-3, again the button invokes a function that looks at other elements in the form. Pass the form object.**

```

<HTML>
<HEAD>
<TITLE>Extracting Highlighted Radio Button</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function fullName(form) {
 for (var i = 0; i < form.stooges.length; i++) {
 if (form.stooges[i].checked) {
 break
 }
 }
 alert("You chose " + form.stooges[i].value + ".")
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Select your favorite Stooage:
<INPUT TYPE="radio" NAME="stooges" VALUE="Moe Howard"
CHECKED>Moe

```

```
<INPUT TYPE="radio" NAME="stooges" VALUE="Larry Fine"> Larry
<INPUT TYPE="radio" NAME="stooges" VALUE="Curly Howard">
Curly

<INPUT TYPE="button" NAME="Viewer" VALUE="View Full Name..."
onClick="fullName(this.form)">
</FORM>
</BODY>
</HTML>
```

For Listing 9-4, all action is triggered by and confined to the SELECT object. Pass only that object to the function.

```
<HTML>
<HEAD>
<TITLE>Select Navigation</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function goThere(list) {
 location = list.options[list.selectedIndex].value
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Choose a place to go:
<SELECT NAME="urlList" onChange="goThere(this)">
 <OPTION SELECTED VALUE="index.html">Home Page
 <OPTION VALUE="store.html">Shop Our Store
 <OPTION VALUE="policies.html">Shipping Policies
 <OPTION VALUE="http://www.yahoo.com">Search the Web
</SELECT>
</FORM>
</BODY>
</HTML>
```

2. This requires a bit of surgery. The Submit button is replaced with a standard button whose VALUE attribute is set to "Submit." The button's onClick event handler calls the checkForm() function, which performs the validation. If an empty field exists, the function must return to bail out of the loop. Because the event handler is not expecting any returned value, you can simply issue the return statement to stop the function altogether. If all the tests pass, then the form is submitted with the submit() method. Functions that have a return statement inside an if construction must also have a return statement outside the construction so that it always returns a value (including the null value used here). The other change is that the onSubmit event handler has been removed from the <FORM> tag, because it is no longer needed (the submit() method does not trigger an onSubmit event handler).

```
<HTML>
<HEAD>
<TITLE>Validator</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

function checkForm(form) {
 for (var i = 0; i < form.elements.length; i++) {
 if (form.elements[i].value == "") {
 alert("Fill out ALL fields.")
 return
 }
 }
 form.submit()
 return
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Please enter all requested information:

First Name:<INPUT TYPE="text" NAME="firstName">

Last Name:<INPUT TYPE="text" NAME="lastName">

Rank:<INPUT TYPE="text" NAME="rank">

Serial Number:<INPUT TYPE="text" NAME="serialNumber">

Submit Form
</FORM>
</BODY>
</HTML>

```

- 3. The `this` keyword refers to the text field object, so that `this.value` refers to the value property of that object.**

```

function showText(txt) {
 alert(txt)
}

```

- 4. `document.accessories.accl.value = "Leather Carrying Case"`  
`document.forms[1].accl.value = "Leather Carrying Case"`**

- 5. The `SELECT` object invokes a function that does the job.**

```

<HTML>
<HEAD>
<TITLE>Color Changer</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function setColor(list) {
 var newColor = list.options[list.selectedIndex].value
 document.bgColor = newColor
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Select a background color:
<SELECT onChange="setColor(this)">
<OPTION VALUE="red">Stop
<OPTION VALUE="yellow">Caution
<OPTION VALUE="green">Go

```

```

</SELECT>
</FORM>
</BODY>
</HTML>

```

## Chapter 10 Answers

1. Use `string.indexOf()` to see if the field contains the “@” symbol.

```

<HTML>
<HEAD>
<TITLE>E-mail Validator</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function checkAddress(form) {
 if (form.email.value.indexOf("@") == -1) {
 alert("Check the e-mail address for accuracy.")
 return false
 }
 return true
}
</SCRIPT>
</HEAD>

<BODY>
<FORM onSubmit="return checkAddress(this)">
Enter your e-mail address:
<INPUT TYPE="text" NAME="email" SIZE=30>

<INPUT TYPE="submit">
</FORM>
</BODY>
</HTML>

```

2. Remember that the `substring` goes up to, but does not include, the index of the second parameter. Spaces count as characters.

```

myString.substring(0,3) // result = "Net"
myString.substring(13,18) // result = "gator"
myString.substring(4,12) // result = "cape Nav"

```

3. The missing `for` loop is in boldface. You could also use the increment operator on the count variable (`++count`) to add 1 to it for each letter “e.”

```

function countE(form) {
 var count = 0
 var inputString = form.mainstring.value.toLowerCase()
 for (var i = 0; i < inputString.length; i++) {
 if (inputString.charAt(i) == "e") {
 count += 1
 }
 }
 var msg = "The string has " + count
 msg += " instances of the letter e."
 alert(msg)
}

```

**4. The formula for the random throw of one die is in the chapter.**

```

<HTML>
<HEAD>
<TITLE>E-mail Validator</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function roll(form) {
 form.die1.value = Math.floor(Math.random() * 6) + 1
 form.die2.value = Math.floor(Math.random() * 6) + 1
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<INPUT TYPE="text" NAME="die1" SIZE=2>
<INPUT TYPE="text" NAME="die2" SIZE=2>

<INPUT TYPE="button" VALUE="Roll the Dice"
onClick="roll(this.form)">
</FORM>
</BODY>
</HTML>

```

**5. If you used the `Math.round()` method in your calculations, that is fine for your current exposure to the `Math` object. Another method, `Math.ceil()`, may be more valuable because it rounds up any fractional value.**

```

<HTML>
<HEAD>
<TITLE>Waiting for Santa</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function daysToXMAS() {
 var oneDay = 1000 * 60 * 60 * 24
 var today = new Date()
 var XMAS = new Date("December 25, 2001")
 var diff = XMAS.getTime() - today.getTime()
 return Math.ceil(diff/oneDay)
}
</SCRIPT>
</HEAD>

<BODY>
<SCRIPT LANGUAGE="JavaScript">
document.write(daysToXMAS() + " days until Christmas.")
</SCRIPT>
</BODY>
</HTML>

```

## Chapter 11 Answers

1. `onLoad="parent.currCourse = 'history101'"`
- 2.

3. All three frames are siblings, so references include the parent.
 

```

parent.mechanics.location.href = "french201M.html"
parent.description.location.href = "french201D.html"

```
4. A script in one of the documents is attempting to reference the selector object in one of the frames but the document has not fully loaded, causing the object to not yet be in the browser's object model. Rearrange the script so that it fires in response to the `onLoad` event handler of the framesetting document.
5. From the subwindow, the `opener` property refers back to the frame containing the window.open() method. To extend the reference to the frame's parent, the reference includes both pieces: `opener.parent.ObjVarFuncName`.

## Chapter 12 Answers

1. As the document loads, the `<IMG>` tag creates a document image object. A memory image object is created with the new `Image()` constructor. Both objects have the same properties, and assigning a URL to the `src` property of a memory object loads the image into the browser's image cache.
2. 

```
var janeImg = new Image(100,120)
janeImg.src = "jane.jpg"
```
3. 

```
document.images["people"].src = janeImg.src
```
4. Surround `<IMG>` tags with `link (A element)` tags, and use the link's `onClick`, `onMouseOver`, and `onMouseOut` event handlers. Set the image's `BORDER` attribute to zero if you don't want the link highlight to appear around the image.

# JavaScript and DOM Internet Resources

---

**A**s an online technology, JavaScript has plenty of support online for scripters. Items recommended here were taken as a snapshot of Internet offerings in early 2001. But beware! Sites change. URLs change. Be prepared to hunt around for these items if the information provided here becomes out-of-date by the time you read this.

## Support and Updates for this Book

The most up-to-date list of errata and other notes of interest pertaining to this edition of the *JavaScript Bible* can be found at the official Support Center, located at:

<http://www.dannyg.com/update.html>

If you are experiencing difficulty with the example listings in this book, first check with the Support Center to see if your question has been answered. As mentioned earlier, you are encouraged to enter the tutorial listings yourself to get used to typing JavaScript (and HTML) code. If, after copying the examples from Part II, you can't make something work (and a fix hasn't already been posted to the Support Center), send the file you've typed to me via e-mail, along with a description of what's not working for you. Also tell me the browser version and operating system that you're using. My e-mail address is [dannyg@dannyg.com](mailto:dannyg@dannyg.com). Regretfully, I am unable to answer general questions about JavaScript or how to apply examples from the book to your own projects.

## Newsgroups

The best places to get quick answers to your pressing questions are online newsgroups. Here are the top JavaScript-related newsgroups:

On most news servers:

`comp.lang.javascript`

On `news://msnews.microsoft.com`

`microsoft.public.scripting.jscript`  
`microsoft.public.windows.inetexplorer.ie5.programming.dhtml`  
`microsoft.public.windows.inetexplorer.ie5.programming.dhtml.scripting`  
`microsoft.public.inetsdk.programming.scripting.jscript`

On `news://secnews.netscape.com`

`netscape.public.mozilla.dom`  
`netscape.public.mozilla.jseng`

Before you post a question to a newsgroup, however, read about FAQs in the following section and also use the extremely valuable [Deja.com](http://dejanews.com) newsgroup archive, which is now owned by Google. Look for links to “Usenet Advanced Search” at:

<http://groups.google.com>

Enter the keyword or phrase into the top text box, but then also try to narrow your search by limiting the newsgroup(s) to search. For example, if you have a question about weird behavior you are experiencing with the `borderCollapse` style property in IE, enter `borderCollapse` into the keyword field, and then first try narrowing the search to the newsgroup `comp.lang.javascript`. If you don’t find the answer there, try again with all the Microsoft newsgroups by specifying `microsoft.public.*` in the Newsgroups field.

If you post a question to a newsgroup, you will most likely get a quick and intelligent response if you also provide either some sample code that’s giving you a problem, or a link to a temporary file on your server that others can check out. Visualizing a problem you’ve spent days on is very hard for others. Be as specific as possible, including the browser(s) on which the code must run and the nature of the problem.

## FAQs

One situation that arises with a popular and accessible technology, such as JavaScript and DHTML authoring, is that the same questions get asked over and over, as newcomers arrive on the scene daily. Rather than invoke the ire of newsgroup users, look through existing FAQ files to see if your concern has already been raised and answered. Here are some of the best JavaScript FAQ sites:

[javascript.faqts.com](http://javascript.faqts.com)  
[developer.irt.org/script/script.htm](http://developer.irt.org/script/script.htm)

For less-frequently asked questions—but previously asked and answered in a public form—use the [dejanews.com](http://dejanews.com) archive search, described earlier in this appendix.

## Online Documentation

Locations of Web sites that dispense official documentation for one browser or another are extremely fluid. Therefore, the following information contains links only to top-level areas of appropriate Web sites, along with tips on what to look for after you are at the site.

For Netscape browser technologies, start at:

<http://developer.netscape.com/library/>

You can also find some interesting future-oriented developer documentation at:

<http://www.mozilla.org/docs>

Microsoft has condensed its developer documentation into a massive site called MSDN (Microsoft Developer Network). The place to begin is:

<http://msdn.microsoft.com/workshop/>

This page is the portal to many technologies, but the one most applicable to JavaScript and client-side scripting is one labeled “DHTML, HTML & CSS”. Look for subject headers covering Document Object Model and DHTML References. The core JScript language is detailed in a separate section:

<http://msdn.microsoft.com/scripting/jscript/techinfo/jsdocs.htm>

Finally, you can read the industry standards for HTML, CSS, and ECMAScript technologies online. Be aware that these documents are primarily intended for developers of tools that we use—browsers, WYSIWYG editors, and so forth—to direct them on how their products should respond to tags, style sheets, scripts, and so on. Reading these documents has frequently been cited as a cure for insomnia.

<http://www.ecma.ch/ecma1/STAND/ECMA-262.HTM>

<http://www.w3.org/TR/html4>

<http://www.w3.org/TR/REC-CSS2>

Please note that just because a particular item is described in an industry standard doesn't mean that it is implemented in any or all browsers. In the real world, we must develop for the way the technologies are actually implemented in browsers.

## World Wide Web

The number of Web sites devoted to JavaScript tips and tricks is mind-boggling. Many sites come and go in the middle of the night, leaving no trace of their former existence. If you are looking for more example code for applications not covered in this book, perhaps the best place to begin your journey is through the traditional search engines. Narrowing your search through careful keyword choice is vital. In addition to the Netscape and (heavily Windows-oriented) Microsoft developer Web sites (plus numerous online articles of mine listed at <http://www.dannyg.com/recentwriting.html>), a couple other venerable sites are:

<http://builder.com>

<http://www.webreference.com>

These sites are by no means the only worthwhile JavaScript and DHTML destinations on the Web. Sometimes having too many sources is as terrifying as having not enough. The links and newsgroups described in this appendix should take you a long way.

# What's on the CD-ROM

---

**T**he accompanying Windows–Macintosh CD-ROM contains nearly 300 HTML Document listings from the book, substantial supplemental book material, electronic versions of the Quick Reference shown in Appendix A, a complete, searchable version of the book, trial software, and the Adobe Acrobat Reader.

## System Requirements

To derive the most benefit from the example Listings, you should have both Netscape Navigator 6 (or later) and Internet Explorer 5 (or later) installed on your computer. While many scripts run in both browsers, several scripts demonstrate features that are available on only one browser or the other. To write scripts, you can use a simple text editor, word processor, or dedicated HTML editor.

To use the Adobe Acrobat Reader, you need the following:

- ◆ For Windows 95, Windows 98, or Windows NT4.0 (with SP3 or later), you should be using a 486 or Pentium computer with 16MB of RAM and 10MB of hard disk space.
- ◆ Macintosh users require a PowerPC, System 7.1,2 or later, at least 8MB of RAM, and 8MB of disk space.

## Disc Contents

Platform-specific software is located in the appropriate Windows and Macintosh directories on the CD-ROM. The contents include the following items.

### JavaScript listings for Windows and Macintosh text editors

Starting with Part III of the book, almost all example listings are on the CD-ROM in the form of complete HTML files, which

you can load into a browser to see the language item in operation. A directory called Listings contains the HTML and related files, with nested folders named for each chapter. Each HTML file's name is keyed to the Listing number in the book. For example, the file for Listing 15-1 is named `lst15-01.htm`. Note that no listings are provided for the tutorial chapters of Part II, because you are encouraged to enter HTML and scripting code manually.

For your convenience, an `index.html` file in the Listings folder provides a front-end table of contents to the HTML files for the book's program listings. Open that file from your browser whenever you want to access the program listing files. If you intend to access that index page frequently, you can bookmark it in your browser(s). Using the index file to access the listing files can be very important in some cases, because several individual files must be opened within their associated framesets to work properly. Accessing the files through the `index.html` file assures that you open the frameset. The `index.html` file also shows browser compatibility ratings for all the listings. This saves you time from opening listings that are not intended to run on your browser. To examine and modify the HTML source files, open them from your favorite text editor program (for Windows editors, be sure to specify the `.htm` file extension in the Open File dialog box).

You can open all listing files directly from the CD-ROM, but if you copy them to your hard drive, access is faster and you will be able to experiment with modifying the files more readily. Copy the folder named Listings from the CD-ROM to any location on your hard drive.

## JavaScript and Browser Object Quick Reference from Appendix A (Adobe Acrobat format)

If you like the Quick Reference in Appendix A, you can print it out in your choice of format with the help of the Adobe Acrobat Reader, included with the CD-ROM. The files are located on the CD-ROM in the `:Author_Files:JS Object Reference:` folder in PDF format. To decide on the format that is best for you, read the file named `Choose a Version.txt`. The `.pdf` file for each version is contained in its own subdirectory, where you also find full assembly and collating instructions in a companion text file. Start Acrobat Reader on your computer and open the desired file from either the CD-ROM or from a copy made to your hard drive. Before printing out the document, be sure to choose Landscape orientation in the Page Setup dialog box of Acrobat Reader.

## Adobe Acrobat Reader

The Adobe Acrobat Reader is a helpful program that enables you to view the reference example sections for Parts III and IV of the book, the Quick Reference from Appendix A, and the searchable version of this book, all of which are in `.pdf` format on the CD-ROM. To install and run Adobe Acrobat Reader, follow these steps:

### For Windows

1. Start Windows Explorer or Windows NT Explorer and then open the Acrobat folder on the CD-ROM.
2. In the Acrobat folder, double-click `rs405eng.exe` and follow the instructions presented on-screen for installing Adobe Acrobat Reader.

## For Macintosh

1. Open the Acrobat folder on the CD-ROM.
2. In the Acrobat folder, double-click the Adobe Acrobat Installer icon and follow the instructions presented on-screen for installing Adobe Acrobat Reader.

## Reference example sections from Parts III and IV

In many places throughout the reference chapters of Parts III and IV, you see an icon that directs you to the CD-ROM for an example of the language term being discussed. All of these example sections are collected into Appendix F, which is located on the CD-ROM and is part of the book's .pdf file. For the fastest access to these example sections, copy the Examples directory and its contents to your hard disk.

An example may consist of a detailed description of a listing or directions on how to experiment with the term through a handy learning utility on the CD-ROM, called The Evaluator, which is located among the listings for Chapter 15. While many of these example sections contain listings, the Acrobat files are distinct from the HTML listing files that you run in your browser and edit with your text editor.

## Searchable version of the book

This is a complete, searchable version of the book, provided in Adobe Acrobat .pdf format. Access it from the JSB4 folder after installing Adobe Acrobat Reader. To take advantage of the full-text search, you must add the book's index file (.pdx file) to the list of indexes available to your copy of Acrobat Reader. Here are the steps to add the index:

1. Choose Search from the Edit menu.
2. Choose Select Indexes from the submenu.
3. Click the Add button.
4. Locate the .pdx file on the CD-ROM in the directory containing the book's .pdf files and open the .pdx file. The *JavaScript Bible* index should be listed in the Index Selection window. If the checkbox next to the name is not yet checked, check it now.
5. Click OK.

To begin an actual search, click the Search icon (binoculars in front of a sheet of paper). Enter the text for which you're searching. The search also covers the text of example listings. To access the index and search facilities in future sessions, the CD-ROM must be in your CD-ROM drive.

## Commercial software products

Included on the CD-ROM are licensed versions of Microsoft Internet Explorer 5.5 for Windows and both the Windows and Macintosh versions of Netscape Navigator 6.0. These products are included on the CD-ROM for your convenience if you have not yet downloaded the installers for the products from Microsoft or Netscape. Prior to installing either product, be sure that you read and understand the installation instructions.

## Commercial, trial, and shareware software

We also include the following software for your review:

### **Index Stock Imagery WebSpice Objects**

The CD-ROM contains the full version of WebSpice Objects. The product contains 3,000 high-quality buttons, labels, borders, and other art to give the professional look to your Web pages.

### **Helios Software Solutions TextPad 4.3.1 (Windows only)**

TextPad is a favorite Windows text editor for programmers. TextPad is a significant improvement over the Notepad and WordPad editors that come with Windows, but doesn't have all the overhead that you find in word processors. TextPad is shareware. Registration information is included with the product.

### **Bare Bones Software BBEdit 5.1.1 (Macintosh only)**

BBEdit is the most popular text editor for the Macintosh. The version on the CD-ROM is a demo version.

# Examples from Parts III and IV

---

## Chapter 15 Examples

The following section contains examples from Chapter 15,  
“Generic HTML Element Objects.”

A P P E N D I X

# Generic Objects

## Properties

### accessKey

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

When you load the script in Listing 15-1, adjust the height of the browser window so that you can see nothing below the second dividing rule. Enter any character into the Settings portion of the page and press Enter. (The Enter key may cause your computer to beep.) Then hold down the Alt (Windows) or Ctrl (Mac) key while pressing the same keyboard key. The element from below the second divider should come into view.

#### Listing 15-1: Controlling the accessKey Property

```
<HTML>
<HEAD>
<TITLE>accessKey Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function assignKey(type, elem) {
 if (window.event.keyCode == 13) {
 switch (type) {
 case "button":
 document.forms["output"].access1.accessKey = elem.value
 break
 case "text":
 document.forms["output"].access2.accessKey = elem.value
 break
 case "table":
 document.all.myTable.accessKey = elem.value
 }
 return false
 }
}
</SCRIPT>
</HEAD>
<BODY>
```

```

<H1>accessKey Property Lab</H1>
<HR>
Settings:

<FORM NAME="input">
Assign an accessKey value to the Button below and press Return:
<INPUT TYPE="text" SIZE=2 MAXLENGTH=1
onKeyPress="return assignKey('button', this)">

Assign an accessKey value to the Text Box below and press Return:
<INPUT TYPE="text" SIZE=2 MAXLENGTH=1
onKeyPress="return assignKey('text', this)">

Assign an accessKey value to the Table below (IE5.5 only) and press Return:
<INPUT TYPE="text" SIZE=2 MAXLENGTH=1
onKeyPress="return assignKey('table', this)">
</FORM>

Then press Alt (Windows) or Control (Mac) + the key.

<I>Size the browser window to view nothing lower than this line.</I>
<HR>

<FORM NAME="output" onSubmit="return false">
<INPUT TYPE="button" NAME="access1" VALUE="Standard Button">
<P></P>
<INPUT TYPE="text" NAME="access2">
<P></P>
</FORM>
<TABLE ID="myTable" CELLPADDING="10" BORDER=2>
<TR>
<TH>Quantity<TH>Description<TH>Price
</TR>
<TR>
<TBODY BGCOLOR="red">
<TR>
<TD WIDTH=100>4<TD>Primary Widget<TD>$14.96
</TR>
<TR>
<TD>10<TD>Secondary Widget<TD>$114.96
</TR>
</TBODY>
</TABLE>

</BODY>
</HTML>

```

**Note**

In IE5, the keyboard combination may bring focus to the input field. This anomalous behavior does not affect the normal script setting of the `accessKey` property.

## all

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

Use The Evaluator (Chapter 13) to experiment with the `all` collection. Enter the following statements one at a time into the lower text box, and review the results in the textarea for each.

```
document.all
myTable.all
myP.all
```

If you encounter a numbered element within a collection, you can explore that element to see which tag is associated with it. For example, if one of the results for the `document.all` collection says `document.all.8=[object]`, enter the following statement into the topmost text box:

```
document.all[8].tagName
```

## attributes

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

**Example**

Use The Evaluator (Chapter 13) to examine the values of the `attributes` array for some of the elements in that document. Enter each of the following expressions into the lower text field, and see the array contents in the Results textarea for each:

```
document.body.attributes
document.getElementById("myP").attributes
document.getElementById("myTable").attributes
```

If you have both NN6 and IE5, compare the results you get for each of these expressions. To view the properties of a single attribute in IE5/Windows, enter the following statement into the bottom text field:

```
document.getElementById("myP").attributes["class"]
```

For NN6 and IE5/Mac, use the W3C DOM syntax:

```
document.getElementById("myP").attributes.getItem("class")
```

## behaviorUrns

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

The following function is embedded within a more complete example of IE/Windows HTML behaviors (Listing 15-19 in this chapter). It reports the length of the `behaviorUrns` array and shows — if the values are returned — the URL of the attached behavior.

```
function showBehaviors() {
 var num = document.all.myP.behaviorUrns.length
 var msg = "The myP element has " + num + " behavior(s). "
 if (num > 0) {
 msg += "Name(s): \r\n"
 for (var i = 0; i < num; i++) {
 msg += document.all.myP.behaviorUrns[i] + "\r\n"
 }
 }
 alert(msg)
}
```

## canHaveChildren

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-2 uses color to demonstrate the difference between an element that can have children and one that cannot. The first button sets the `color` style property of every visible element on the page to red. Thus, elements (including the normally

non-childbearing ones such as HR and INPUT) are affected by the color change. But if you reset the page and click the largest button, only those elements that contain nested elements receive the color change.

### Listing 15-2: Reading the canHaveChildren Property

```

<HTML>
<HEAD>
<TITLE>canHaveChildren Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function colorAll() {
 for (var i = 0; i < document.all.length; i++) {
 document.all[i].style.color = "red"
 }
}

function colorChildBearing() {
 for (var i = 0; i < document.all.length; i++) {
 if (document.all[i].canHaveChildren) {
 document.all[i].style.color = "red"
 }
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>canHaveChildren Property Lab</H1>
<HR>
<FORM NAME="input">
<INPUT TYPE="button" VALUE="Color All Elements" onClick="colorAll()">

<INPUT TYPE="button" VALUE="Reset" onClick="history.go(0)">

<INPUT TYPE="button" VALUE="Color Only Elements That Can Have Children"
onClick="colorChildBearing()">
</FORM>

<HR>

<FORM NAME="output">
<INPUT TYPE="checkbox" CHECKED>Your basic checkbox
<P></P>
<INPUT TYPE="text" NAME="access2" VALUE="Some textbox text.">
<P></P>
</FORM>
<TABLE ID="myTable" CELLPADDING="10" BORDER=2>
<TR>
<TH>Quantity<TH>Description<TH>Price
</TR>

```

```

<TBODY>
<TR>
 <TD WIDTH=100>4<TD>Primary Widget<TD>$14.96
</TR>
<TR>
 <TD>10<TD>Secondary Widget<TD>$114.96
</TR>
</TBODY>
</TABLE>

</BODY>
</HTML>

```

## canHaveHTML

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `canHaveHTML` property. Enter the following statements into the top text field and observe the results:

```

document.all.input.canHaveHTML
document.all.myP.canHaveHTML

```

The first statement returns `false` because an `INPUT` element (the top text field in this case) cannot have nested HTML. But the `myP` element is a `P` element that gladly accepts HTML content.

## childNodes

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	

### Example

The `walkChildNodes()` function shown in Listing 15-3 accumulates and returns a hierarchical list of child nodes from the point of view of the document's HTML element

(the default) or any element whose ID you pass as a string parameter. This function is embedded in The Evaluator so that you can inspect the child node hierarchy of that page or (when using `evaluator.js` for debugging as described in Chapter 45) the node hierarchy within any page you have under construction. Try it out in The Evaluator by entering the following statements into the top text field:

```
walkChildNodes()
walkChildNodes(getElementById("myP"))
```

The results of this function show the nesting relationships among all child nodes within the scope of the initial object. It also shows the act of drilling down to further `childNodes` collections until all child nodes are exposed and catalogued. Text nodes are labeled accordingly. The first 15 characters of the actual text are placed in the results to help you identify the nodes when you compare the results against your HTML source code. The early NN6 phantom text nodes that contain carriage returns display `<cr>` in the results for each return character.

### Listing 15-3: Collecting Child Nodes

```
function walkChildNodes(objRef, n) {
 var obj
 if (objRef) {
 if (typeof objRef == "string") {
 obj = document.getElementById(objRef)
 } else {
 obj = objRef
 }
 } else {
 obj = (document.body.parentElement) ?
 document.body.parentElement : document.body.parentNode
 }
 var output = ""
 var indent = ""
 var i, group, txt
 if (n) {
 for (i = 0; i < n; i++) {
 indent += "+---"
 }
 } else {
 n = 0
 output += "Child Nodes of <" + obj.tagName
 output += ">\n=====\\n"
 }
 group = obj.childNodes
 for (i = 0; i < group.length; i++) {
 output += indent
 switch (group[i].nodeType) {
```

```

 case 1:
 output += "<" + group[i].tagName
 output += (group[i].id) ? " ID=" + group[i].id : ""
 output += (group[i].name) ? " NAME=" + group[i].name : ""
 output += ">\n"
 break
 case 3:
 txt = group[i].nodeValue.substr(0,15)
 output += "[Text:\\" + txt.replace(/[\r\n]/g,"
")
 if (group[i].nodeValue.length > 15) {
 output += "..."
 }
 output += "\"]\n"
 break
 case 8:
 output += "[!COMMENT!]\n"
 break
 default:
 output += "[Node Type = " + group[i].nodeType + "]\n"
}
if (group[i].childNodes.length > 0) {
 output += walkChildNodes(group[i], n+1)
}
}
return output
}

```

## children

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The `walkChildren()` function shown in Listing 15-4 accumulates and returns a hierarchical list of child elements from the point of view of the document's HTML element (the default) or any element whose ID you pass as a string parameter. This function is embedded in The Evaluator so that you can inspect the parent-child hierarchy of that page or (when using `evaluator.js` for debugging as described in Chapter 45) the element hierarchy within any page you have under construction. Try it out in The Evaluator in IE5+ by entering the following statements into the top text field:

```
walkChildren()
walkChildren("myP")
```

The results of this function show the nesting relationships among all parent and child elements within the scope of the initial object. It also shows the act of drilling down to further children collections until all child elements are exposed and catalogued. The element tags also display their ID and/or NAME attribute values if any are assigned to the elements in the HTML source code.

### Listing 15-4: Collecting Child Elements

```
function walkChildren(objRef, n) {
 var obj
 if (objRef) {
 if (typeof objRef == "string") {
 obj = document.getElementById(objRef)
 } else {
 obj = objRef
 }
 } else {
 obj = document.body.parentElement
 }
 var output = ""
 var indent = ""
 var i, group
 if (n) {
 for (i = 0; i < n; i++) {
 indent += "+---"
 }
 } else {
 n = 0
 output += "Children of <" + obj.tagName
 output += ">\n=====\\n"
 }
 group = obj.children
 for (i = 0; i < group.length; i++) {
 output += indent + "<" + group[i].tagName
 output += (group[i].id) ? " ID=" + group[i].id : ""
 output += (group[i].name) ? " NAME=" + group[i].name : ""
 output += ">\n"
 if (group[i].children.length > 0) {
 output += walkChildren(group[i], n+1)
 }
 }
 return output
}
```

## className

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The style of an element toggles between “on” and “off” in Listing 15-5 by virtue of setting the element’s `className` property alternatively to an existing style sheet class selector name and an empty string. When you set the `className` to an empty string, the default behavior of the H1 element governs the display of the first header. A click of the button forces the style sheet rule to override the default behavior in the first H1 element.

### Listing 15-5: Working with the className Property

```
<HTML>
<HEAD>
<TITLE>className Property</TITLE>
<STYLE TYPE="text/css">
.special {font-size:16pt; color:red}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function toggleSpecialStyle(elemID) {
 var elem = (document.all) ? document.all(elemID) :
document.getElementById(elemID)
 if (elem.className == "") {
 elem.className = "special"
 } else {
 elem.className = ""
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>className Property Lab</H1>
<HR>
<FORM NAME="input">
<INPUT TYPE="button" VALUE="Toggle Class Name"
onClick="toggleSpecialStyle('head1')">
</FORM>

<H1 ID="head1">ARTICLE I</H1>
```

*Continued*

**Listing 15-5 (continued)**

```
<P>Congress shall make no law respecting an establishment of religion, or
prohibiting the free exercise thereof; or abridging the freedom of speech, or of
the press; or the right of the people peaceably to assemble, and to petition the
government for a redress of grievances.</P>
```

```
<H1>ARTICLE II</H1>
```

```
<P>A well regulated militia, being necessary to the security of a free state,
the right of the people to keep and bear arms, shall not be infringed.</P>
```

```
</BODY>
```

```
</HTML>
```

You can also create multiple versions of a style rule with different class selector identifiers and apply them at will to a given element.

`clientHeight`  
`clientWidth`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

Listing 15-6 calls upon the `clientHeight` and `clientWidth` properties of a DIV element that contains a paragraph element. Only the width of the DIV element is specified in its style sheet rule, which means that the paragraph's text wraps inside that width and extends as deeply as necessary to show the entire paragraph. The `clientHeight` property describes that depth. The `clientHeight` property then calculates where a logo image should be positioned immediately after DIV, regardless of the length of the text. As a bonus, the `clientWidth` property helps the script center the image horizontally with respect to the paragraph's text.

**Listing 15-6: Using `clientHeight` and `clientWidth` Properties**

```
<HTML>
<HEAD>
<TITLE>clientHeight and clientWidth Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

function showLogo() {
 var paragraphW = document.all.myDIV.clientWidth
 var paragraphH = document.all.myDIV.clientHeight
 // correct for Windows/Mac discrepancies
 var paragraphTop = (document.all.myDIV.clientTop) ?
 document.all.myDIV.clientTop : document.all.myDIV.offsetTop
 var logoW = document.all.logo.style.pixelWidth
 // center logo horizontally against paragraph
 document.all.logo.style.pixelLeft = (paragraphW-logoW)/2
 // position image immediately below end of paragraph
 document.all.logo.style.pixelTop = paragraphTop + paragraphH
 document.all.logo.style.visibility = "visible"
}
</SCRIPT>
</HEAD>
<BODY>
<BUTTON onClick="showLogo()">Position and Show Logo Art</BUTTON>
<DIV ID="logo" STYLE="position:absolute; width:120px; visibility:hidden"></DIV>
<DIV ID="myDIV" STYLE="width:200px">
<P>Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do eiusmod
tempor incididunt ut labore et dolore magna aliqua. Ut enim adminim veniam, quis
nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.
Duis aute irure dolor in reprehenderit involuptate velit esse cillum dolore eu
fugiat nulla pariatur. Excepteur sint occaecat cupidatat non proident.</P>
</DIV>
</BODY>
</HTML>

```

To assist in the vertical positioning of the logo, the `offsetTop` property of the DIV object provides the position of the start of the DIV with respect to its outer container (the BODY). Unfortunately, IE/Mac uses the `clientTop` property to obtain the desired dimension. That measure (assigned to the `paragraphTop` variable), plus the `clientHeight` of the DIV, provides the top coordinate of the image.

If you use only IE5, you can eliminate the DIV wrapper around the P element and assign the `STYLE` attribute directly to the P element. The script can then read the `clientHeight` and `clientWidth` of the P object.

## contentEditable

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

## Example

Listing 15-7 is a simplified demonstration of how to turn some text inside a document into an editable element. When you click the button of a freshly loaded page, the `toggleEdit()` function captures the opposite of the current editable state via the `isContentEditable` property of the DIV that is subject to edit. You switch on editing for that element in the next statement by assigning the new value to the `contentEditable` property of the DIV. For added impact, turn the text of the DIV to red to provide additional user feedback about what is editable on the page. You can also switch the button label to one that indicates the action invoked by the next click on it.

### Listing 15-7: Using the `contentEditable` Property

```
<HTML>
<HEAD>
<STYLE TYPE="text/css">
.normal {color: black}
.editing {color: red}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function toggleEdit() {
 var newState = !editableText.isContentEditable
 editableText.contentEditable = newState
 editableText.className = (newState) ? "editing" : "normal"
 editBtn.innerText = (newState) ? "Disable Editing" : "Enable Editing"
}
</SCRIPT>
<BODY>
<H1>Editing Contents</H1>
<HR>
<P>Turn on editing to modify the following text:</P>
<DIV ID="editableText">Edit this text on the fly...</DIV>
<P><BUTTON ID="editBtn" onClick="toggleEdit()" onFocus="this.blur()">
Enable Editing
</BUTTON></P>
</BODY>
</HTML>
```

The `BUTTON` element has an `onFocus` event handler that immediately invokes the `blur()` method on the button. This prevents a press of the spacebar (during editing) from accidentally triggering the button.

## currentStyle

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to compare the properties of the `currentStyle` and `style` objects of an element. For example, an unmodified copy of The Evaluator contains an EM element whose ID is "myEM". Enter `document.all.myEM.style` into the bottom property listing text box and press Enter. Notice how most of the property values are empty. Now enter `document.all.myEM.currentStyle` into the property listing text box and press Enter. Every property has a value associated with it.

## dataFld dataFormatAs dataSrc

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 15-8 is a simple document that has two TDC objects associated with it. The external files are different formats of the U.S. Bill of Rights document. One file is a traditional, tab-delimited data file consisting of only two records. The first record is a tab-delimited sequence of field names (named "Article1", "Article2", and so on); the second record is a tab-delimited sequence of article content defined in HTML:

```
<H1>ARTICLE I</H1><P>Congress shall make...</P>
```

The second file is a raw text file consisting of the full Bill of Rights with no HTML formatting attached.

When you load Listing 15-8, only the first article of the Bill of Rights appears in a blue-bordered box. Buttons enable you to navigate to the previous and next articles in the series. Because the data source is a traditional, tab-delimited file, the `nextField()` and `prevField()` functions calculate the name of the next source field and assign the new value to the `dataFld` property. All of the data is already in the browser after the page loads, so cycling through the records is as fast as the browser can reflow the page to accommodate the new content.

### Listing 15-8: Changing `dataFld` and `dataSrc` Properties

```
<HTML>
<HEAD>
<TITLE>Data Binding</TITLE>
<STYLE TYPE="text/css">
#display {width:500px; border:10px ridge blue; padding:20px}
.hiddenControl {display:none}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function nextField() {
 var elem = document.all.display
 var fieldName = elem.dataFld
 var currFieldNum = parseInt(fieldName.substring(7, fieldName.length),10)
 currFieldNum = (currFieldNum == 10) ? 1 : ++currFieldNum
 elem.dataFld = "Article" + currFieldNum
}
function prevField() {
 var elem = document.all.display
 var fieldName = elem.dataFld
 var currFieldNum = parseInt(fieldName.substring(7, fieldName.length),10)
 currFieldNum = (currFieldNum == 1) ? 10 : --currFieldNum
 elem.dataFld = "Article" + currFieldNum
}

function toggleComplete() {
 if (document.all.buttonWrapper.className == "") {
 document.all.display.dataSrc = "#rights_raw"
 document.all.display.dataFld = "column1"
 document.all.display.dataFormatAs = "text"
 document.all.buttonWrapper.className = "hiddenControl"
 } else {
 document.all.display.dataSrc = "#rights_html"
 document.all.display.dataFld = "Article1"
 document.all.display.dataFormatAs = "HTML"
 document.all.buttonWrapper.className = ""
 }
}
</SCRIPT>
</HEAD>
```

```

<BODY>
<P>U.S. Bill of Rights</P>
<FORM>
<INPUT TYPE="button" VALUE="Toggle Complete/Individual"
onClick="toggleComplete()"

<INPUT TYPE="button" VALUE="Prev" onClick="prevField()">
<INPUT TYPE="button" VALUE="Next" onClick="nextField()">

</FORM>

<DIV ID="display" DATASRC="#rights_html" DATAFLD="Article1"
DATAFORMATAS="HTML"></DIV>

<OBJECT ID="rights_html" CLASSID="clsid:333C7BC4-460F-11D0-BC04-0080C7055A83">
 <PARAM NAME="DataURL" VALUE="Bill of Rights.txt">
 <PARAM NAME="UseHeader" VALUE="True">
 <PARAM NAME="FieldDelim" VALUE="	">
</OBJECT>
<OBJECT ID="rights_raw" CLASSID="clsid:333C7BC4-460F-11D0-BC04-0080C7055A83">
 <PARAM NAME="DataURL" VALUE="Bill of Rights (no format).txt">
 <PARAM NAME="FieldDelim" VALUE="\ ">
 <PARAM NAME="RowDelim" VALUE="\n">
</OBJECT>
</BODY>
</HTML>

```

Another button on the page enables you to switch between the initial piecemeal version of the document and the unformatted version in its entirety. To load the entire document as a single record, the `FieldDelim` and `RowDelim` parameters of the second `OBJECT` element eliminate their default values by replacing them with characters that don't appear in the document at all. And because the external file does not have a field name in the file, the default value (`column1` for the lone column in this document) is the data field. Thus, in the `toggleComplete()` function, the `dataSrc` property is changed to the desired `OBJECT` element ID, the `dataFld` property is set to the correct value for the data source, and the `dataFormatAs` property is changed to reflect the different intention of the source content (to be rendered as HTML or as plain text). When the display shows the entire document, you can hide the two radio buttons by assigning a `className` value to the `SPAN` element that surrounds the buttons. The `className` value is the identifier of the class selector in the document's style sheet. When the `toggleComplete()` function resets the `className` property to empty, the default properties (normal inline display style) take hold.

One further example demonstrates the kind of power available to the TDC under script control. Listing 15-9 displays table data from a tab-delimited file of Academy

Award information. The data file has eight columns of data, and each column heading is treated as a field name: Year, Best Picture, Best Director, Best Director Film, Best Actress, Best Actress Film, Best Actor, and Best Actor Film. For the design of the page, only five fields from each record appear: Year, Film, Director, Actress, and Actor. Notice in the listing how the HTML for the table and its content is bound to the data source object and the fields within the data.

The “dynamic” part of this example is apparent in how you can sort and filter the data, once loaded into the browser, without further access to the original source data. The TDC object features `Sort` and `Filter` properties that enable you to act on the data currently loaded in the browser. The simplest kind of sorting indicates on which field (or fields via a semicolon delimited list of field names) the entire data set should be sorted. Leading the name of the sort field is either a plus (to indicate ascending) or minus (descending) symbol. After setting the data object’s `Sort` property, invoke its `Reset()` method to tell the object to apply the new property. The data in the bound table is immediately redrawn to reflect any changes.

Similarly, you can tell a data collection to display records that meet specific criteria. In Listing 15-9, two select lists and a pair of radio buttons provide the interface to the `Filter` property’s settings. For example, you can filter the output to display only those records in which the Best Picture was the same picture of the winning Best Actress’s performance. Simple filter expressions are based on field names:

```
dataObj.Filter = "Best Picture" = "Best Actress Film"
```

### Listing 15-9: Sorting and Filtering Bound Data

```
<HTML>
<HEAD>
<TITLE>Data Binding–Sorting</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function sortByYear(type) {
 oscars.Sort = (type == "normal") ? "-Year" : "+Year"
 oscars.Reset()
}
function filterInCommon(form) {
 var filterExpr1 = form.filter1.options[form.filter1.selectedIndex].value
 var filterExpr2 = form.filter2.options[form.filter2.selectedIndex].value
 var operator = (form.operator[0].checked) ? "=" : "<>"
 var filterExpr = filterExpr1 + operator + filterExpr2
 oscars.Filter = filterExpr
 oscars.Reset()
}
</SCRIPT>

</HEAD>
<BODY>
```

```

<P>Academy Awards 1978-1997</P>
<FORM>
<P>Sort list by year from newest to
oldest or from oldest to
newest.</P>
<P>Filter listings for records whose
<SELECT NAME="filter1" onChange="filterInCommon(this.form)">

## dir

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Changing this property value in a standard U.S. version of the browser only makes the right margin the starting point for each new line of text (in other words, the characters are not rendered in reverse order). You can experiment with this in The Evaluator by entering the following statements into the expression evaluation field:

```
document.getElementById("myP").dir = "rtl"
```

## disabled

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				(✓)			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `disabled` property on both form elements (IE4+) and regular HTML elements (IE5.5). For IE4+ and NN6, see what happens when you disable the output textarea by entering the following statement into the top text box:

```
document.forms[0].output.disabled = true
```

The textarea is disabled for user entry, although you can still set the field's `value` property via script (which is how the `true` returned value got there).

If you have IE5.5+, disable the `myP` element by entering the following statement into the top text box:

```
document.all.myP.disabled = true
```

The sample paragraph's text turns gray.

## document

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

The following simplified function accepts a parameter that can be any object in a document hierarchy. The script finds out the reference of the object's containing document for further reference to other objects:

```
function getCompanionFormCount(obj) {
 var ownerDoc = obj.document
 return ownerDoc.forms.length
}
```

Because the `ownerDoc` variable contains a valid reference to a document object, the `return` statement uses that reference to return a typical property of the document object hierarchy.

firstChild  
lastChild

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

**Example**

These two properties come in handy for Listing 15-10, whose job it is to either add or replace LI elements to an existing OL element. You can enter any text you want to appear at the beginning or end of the list. Using the `firstChild` and `lastChild` properties simplifies access to the ends of the list. For the functions that replace child nodes, the example uses the `replaceChild()` method. Alternatively for IE4+, you can modify the `innerText` property of the objects returned by the `firstChild` or `lastChild` property. This example is especially interesting to watch when you add items to the list: The browser automatically renumbers items to fit the current state of the list.

### Listing 15-10: Using firstChild and lastChild Properties

```

<HTML>
<HEAD>
<TITLE>firstChild and lastChild Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// helper function for prepend() and append()
function makeNewLI(txt) {
 var newItem = document.createElement("LI")
 newItem.innerHTML = txt
 return newItem
}
function prepend(form) {
 var newItem = makeNewLI(form.input.value)
 var firstLI = document.getElementById("myList").firstChild
 document.getElementById("myList").insertBefore(newItem, firstLI)
}
function append(form) {
 var newItem = makeNewLI(form.input.value)
 var lastLI = document.getElementById("myList").lastChild
 document.getElementById("myList").appendChild(newItem)
}
function replaceFirst(form) {
 var newItem = makeNewLI(form.input.value)
 var firstLI = document.getElementById("myList").firstChild
 document.getElementById("myList").replaceChild(newItem, firstLI)
}
function replaceLast(form) {
 var newItem = makeNewLI(form.input.value)
 var lastLI = document.getElementById("myList").lastChild
 document.getElementById("myList").replaceChild(newItem, lastLI)
}
</SCRIPT>

</HEAD>
<BODY>
<H1>firstChild and lastChild Property Lab</H1>
<HR>

<LABEL>Enter some text to add to or replace in the OL element:</LABEL>

<INPUT TYPE="text" NAME="input" SIZE=50>

<INPUT TYPE="button" VALUE="Insert at Top" onClick="prepend(this.form)">
<INPUT TYPE="button" VALUE="Append to Bottom" onClick="append(this.form)">

<INPUT TYPE="button" VALUE="Replace First Item"
onClick="replaceFirst(this.form)">
<INPUT TYPE="button" VALUE="Replace Last Item" onClick="replaceLast(this.form)">
</FORM>
<P></P>
<OL ID="myList">Initial Item 1

```

```

Initial Item 2
Initial Item 3
Initial Item 4

</BODY>
</HTML>

```

## height width

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

The following example increases the width of a table by 10 percent.

```

var tableW = parseInt(document.all.myTable.width)
document.all.myTable.width = (tableW * 1.1) + "%"

```

Because the initial setting for the WIDTH attribute of the TABLE element is set as a percentage value, the script calculation extracts the number from the percentage width string value. In the second statement, the old number is increased by 10 percent and turned into a percentage string by appending the percentage symbol to the value. The resulting string value is assigned to the width property of the table.

## hideFocus

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

Use The Evaluator (Chapter 13) to experiment with the hideFocus property in IE5.5. Enter the following statement into the top text field to assign a tabIndex value to the myP element so that, by default, the element receives focus and the dotted rectangle:

```
document.all.myP.tabIndex = 1
```

Press the Tab key several times until the paragraph receives focus. Now, disable the focus rectangle:

```
document.all.myP.hideFocus = true
```

If you now press the Tab key several times, the dotted rectangle does not appear around the paragraph. To prove that the element still receives focus, scroll the page down to the bottom so that the paragraph is not visible (you may have to resize the window). Click one of the focusable elements at the bottom of the page, and then press the Tab key slowly until the Address field toolbar has focus. Press the Tab key once. The page scrolls to bring the paragraph into view, but there is no focus rectangle around the element.

## id

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Rarely do you need to access this property in a script — unless you write an authoring tool that iterates through all elements of a page to extract the IDs assigned by the author. You can retrieve an object reference once you know the object's `id` property (via the `document.getElementById(elemID)` method). But if for some reason your script doesn't know the ID of, say, the second paragraph of a document, you can extract that ID as follows:

```
var elemID = document.all.tags("P")[1].id
```

## innerHTML innerText

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				(✓)			✓	✓	✓

## Example

The IE4+ page generated by Listing 15-11 contains an `H1` element label and a paragraph of text. The purpose is to demonstrate how the `innerHTML` and `innerText` properties differ in their intent. Two text boxes contain the same combination of text and HTML tags that replaces the inner content of the paragraph's label.

If you apply the default content of the first text box to the `innerHTML` property of the `label1` object, the italic style is rendered as such for the first word. In addition, the text in parentheses is rendered with the help of the small style sheet rule assigned by virtue of the surrounding `<SPAN>` tags. But if you apply that same content to the `innerText` property of the `label` object, the tags are rendered as is.

Use this as a laboratory to experiment with some other content in both text boxes. See what happens when you insert a `<BR>` tag within some text of both text boxes.

### Listing 15-11: Using `innerHTML` and `innerText` Properties

```
<HTML>
<HEAD>
<TITLE>innerHTML and innerText Properties</TITLE>
<STYLE TYPE="text/css">
H1 {font-size:18pt; font-weight:bold; font-family:"Comic Sans MS", Arial, sans-
serif}
.small {font-size:12pt; font-weight:400; color:gray}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">

function setGroupLabelAsText(form) {
 var content = form.textInput.value
 if (content) {
 document.all.label1.innerText = content
 }
}

function setGroupLabelAsHTML(form) {
 var content = form.HTMLInput.value
 if (content) {
 document.all.label1.innerHTML = content
 }
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<P>
```

*Continued*

## Listing 15-11 (continued)

```

<INPUT TYPE="text" NAME="HTMLInput"
VALUE="<I>First</I> Article (of ten)"
SIZE=50>
<INPUT TYPE="button" VALUE="Change Heading HTML"
onClick="setGroupLabelAsHTML(this.form)">
</P>
<P>
<INPUT TYPE="text" NAME="textInput"
VALUE="<I>First</I> Article (of ten)"
SIZE=50>
<INPUT TYPE="button" VALUE="Change Heading Text"
onClick="setGroupLabelAsText(this.form)">
</P>
</FORM>
<H1 ID="label1">ARTICLE I</H1>
<P>
Congress shall make no law respecting an establishment of religion, or
prohibiting the free exercise thereof; or abridging the freedom of speech, or of
the press; or the right of the people peaceably to assemble, and to petition the
government for a redress of grievances.
</P>
</BODY>
</HTML>

```

## isContentEditable

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

**Example**

Use The Evaluator (Chapter 13) to experiment with both the `contentEditable` and `isContentEditable` properties on the `myP` and nested `myEM` elements (reload the page to start with a known version). Check the current setting for the `myEM` element by typing the following statement into the top text field:

```
myEM.isContentEditable
```

This value is `false` because no element upward in the element containment hierarchy is set to be editable yet. Next, turn on editing for the surrounding `myP` element:

```
myP.contentEditable = true
```

At this point, the entire `myP` element is editable because its child element is set, by default, to inherit the edit state of its parent. Prove it by entering the following statement into the top text box:

```
myEM.isContentEditable
```

While the `myEM` element is shown to be editable, no change has accrued to its `contentEditable` property:

```
myEM.contentEditable
```

This property value remains the default `inherit`.

You can see an additional example of these two properties in use in Listing 15-7.

## isDisabled

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

Use The Evaluator (Chapter 13) to experiment with both the `disabled` and `isDisabled` properties on the `myP` and nested `myEM` elements (reload the page to start with a known version). Check the current setting for the `myEM` element by typing the following statement into the top text field:

```
myEM.isDisabled
```

This value is `false` because no element upward in the element containment hierarchy is set for disabling yet. Next, disable the surrounding `myP` element:

```
myP.disabled = true
```

At this point, the entire `myP` element (including its children) is disabled. Prove it by entering the following statement into the top text box:

```
myEM.isDisabled
```

While the `myEM` element is shown as disabled, no change has accrued to its `disabled` property:

```
myEM.disabled
```

This property value remains the default `false`.

## isMultiLine

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

Use The Evaluator (Chapter 13) to read the `isMultiLine` property for elements on that page. Try the following statements in the top text box:

```
document.body.isMultiLine
document.forms[0].input.isMultiLine
myP.isMultiLine
myEM.isMultiLine
```

All but the text field form control report that they are capable of occupying multiple lines.

## isTextEdit

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Good coding practice dictates that your script check for this property before invoking the `createTextRange()` method on any object. A typical implementation is as follows:

```
if (document.all.myObject.isTextEdit) {
 var myRange = document.all.myObject.createTextRange()
 [more statements that act on myRange]
}
```

## lang

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Values for the `lang` property consist of strings containing valid ISO language codes. Such codes have, at the minimum, a primary language code (for example, "fr" for French) plus an optional region specifier (for example, "fr-ch" for Swiss French). The code to assign a Swiss German value to an element looks like the following:

```
document.all.specialSpan.lang = "de-ch"
```

## language

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Although it is unlikely that you will modify this property, the following example shows you how to do it for a table cell object:

```
document.all.cellA3.language = "vbs"
```

## lastChild

See `firstChild`.

## length

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

You can try the following sequence of statements in the top text box of The Evaluator to see how the `length` property returns values (and sets them for some objects). Note that some statements work in only some browser versions.

```
(All browsers) document.forms.length
(All browsers) document.forms[0].elements.length
(NN3+, IE4+) document.images.length
(NN4+) document.layers.length
(IE4+) document.all.length
(IE5+, NN6) document.getElementById("myTable").childNodes.length
```

## nextSibling previousSibling

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

## Example

The following function assigns the same class name to all child nodes of an element:

```
function setAllChildClasses(parentElem, className) {
 var childElem = parentElem.firstChild
 while (childElem.nextSibling) {
 childElem.className = className
 childElem = childElem.nextSibling
 }
}
```

This example is certainly not the only way to achieve the same results. Using a `for` loop to iterate through the `childNodes` collection of the parent element is an equally valid approach.

## nodeName

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

## Example

The following function demonstrates one (not very efficient) way to assign a new class name to every P element in an IE5+ document:

```
function setAllPClasses(className) {
 for (var i = 0; i < document.all.length; i++) {
 if (document.all[i].nodeName == "P") {
 document.all[i].className = className
 }
 }
}
```

A more efficient approach uses the `getElementsByTagName()` method to retrieve a collection of all P elements and then iterate through them directly.

## nodeType

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

## Example

You can experiment with viewing `nodeType` property values in The Evaluator. The P element whose ID is `myP` is a good place to start. The P element itself is a `nodeType` of 1:

```
document.getElementById("myP").nodeType
```

This element has three child nodes: a string of text (`nodeName #text`); an EM element (`nodeName EM`); and the rest of the text of the element content (`nodeName #text`). If you view the `nodeType` of either of the text portions, the value comes back as 3:

```
document.getElementById("myP").childNodes[0].nodeType
```

In NN6 and IE5/Mac, you can inspect the `nodeType` of the one attribute of this element (the ID attribute):

```
document.getElementById("myP").attributes[0].nodeType
```

With NN6 and IE5/Mac, you can see how the document object returns a `nodeType` of 9:

```
document.nodeType
```

When IE5 does not support a `nodeType` constant for a node, its value is sometimes reported as 1. However, more likely the value is undefined.

## nodeValue

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

The first example increases the width of a `TEXTAREA` object by 10 percent. The `nodeValue` is converted to an integer (for NN6's string values) before performing the math and reassignment:

```
function widenCols(textareaElem) {
 var colWidth = parseInt(textareaElem.attributes["cols"].nodeValue, 10)
 textareaElem.attributes["cols"].nodeValue = (colWidth * 1.1)
}
```

The second example replaces the text of an element, assuming that the element contains no further nested elements:

```
function replaceText(elem, newText) {
 if (elem.childNodes.length == 1 && elem.firstChild.nodeType == 3) {
 elem.firstChild.nodeValue = newText
 }
}
```

The function builds in one final verification that the element contains just one child node and that it is a text type. An alternative version of the assignment statement of the second example uses the `innerText` property in IE with identical results:

```
elem.innerText = newText
```

## offsetHeight offsetWidth

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

With IE4+, you can substitute the `offsetHeight` and `offsetWidth` properties for `clientHeight` and `clientWidth` in Listing 15-6. The reason is that the two elements in question have their widths hard-wired in style sheets. Thus, the `offsetWidth` property follows that lead rather than observing the default width of the parent (BODY) element.

With IE5+ and NN6, you can use The Evaluator to inspect the `offsetHeight` and `offsetWidth` property values of various objects on the page. Enter the following statements into the top text box:

```
document.getElementById("myP").offsetWidth
document.getElementById("myEM").offsetWidth
document.getElementById("myP").offsetHeight
document.getElementById("myTable").offsetWidth
```

## offsetLeft offsetTop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

The following IE script statements utilize all four “offset” dimensional properties to size and position a DIV element so that it completely covers a SPAN element located within a P element. This can be for a fill-in-the-blank quiz that provides text entry fields elsewhere on the page. As the user gets an answer correct, the blocking DIV element is hidden to reveal the correct answer.

```
document.all.blocker.style.pixelLeft = document.all.span2.offsetLeft
document.all.blocker.style.pixelTop = document.all.span2.offsetTop
document.all.blockImg.height = document.all.span2.offsetHeight
document.all.blockImg.width = document.all.span2.offsetWidth
```

Because the `offsetParent` property for the SPAN element is the BODY element, the positioned DIV element can use the same positioning context (it’s the default context, anyway) for setting the `pixelLeft` and `pixelTop` style properties. (Remember that positioning properties belong to an element’s style object.) The `offsetHeight` and `offsetWidth` properties can read the dimensions of the SPAN element (the example has no borders, margins, or padding to worry about) and assign them to the dimensions of the image contained by the blocker DIV element.

This example is also a bit hazardous in some implementations. If the text of `span2` wraps to a new line, the new `offsetHeight` value has enough pixels to accommodate both lines. But the `blockImg` and `blocker` DIV elements are block-level elements that render as a simple rectangle. In other words, the `blocker` element doesn't turn into two separate strips to cover the pieces of `span2` that spread across two lines.

## offsetParent

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

You can use the `offsetParent` property to help you locate the position of a nested element on the page. Listing 15-12 demonstrates how a script can “walk” up the hierarchy of `offsetParent` objects in IE for Windows to assemble the location of a nested element on a page. The goal of the exercise in Listing 15-12 is to position an image at the upper-left corner of the second table cell. The entire table is centered on the page.

The `onLoad` event handler invokes the `setImagePosition()` function. The function first sets a Boolean flag that determines whether the calculations should be based on the client or offset sets of properties. IE4/Windows and IE5/Mac rely on client properties, while IE5+/Windows works with the offset properties. The discrepancies even out, however, with the `while` loop. This loop traverses the `offsetParent` hierarchy starting with the `offsetParent` of the cell out to, but not including, the `document.body` object. The `body` object is not included because that is the positioning context for the image. In IE5, the `while` loop executes only once because just the `TABLE` element exists between the cell and the body; in IE4, the loop executes twice to account for the `TR` and `TABLE` elements up the hierarchy. Finally, the cumulative values of left and top measures are applied to the positioning properties of the DIV object's style and the image is made visible.

### Listing 15-12: Using the offsetParent Property

```
<HTML>
<HEAD>
<TITLE>offsetParent Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function setImagePosition(){
 var cElement = document.all.myCell
```

```

// Set flag for whether calculations should use
// client- or offset- property measures. Use
// client- for IE5/Mac and IE4/Windows; otherwise
// use offset- properties. An ugly, but necessary
// workaround.
var useClient = (cElement.offsetTop == 0) ?
 ((cElement.offsetParent.tagName == "TR") ? false : true) : false
if (useClient) {
 var x = cElement.clientLeft
 var y = cElement.clientTop
} else {
 var x = cElement.offsetLeft
 var y = cElement.offsetTop
}
var pElement = document.all.myCell.offsetParent
while (pElement != document.body) {
 if (useClient) {
 x += pElement.clientLeft
 y += pElement.clientTop
 } else {
 x += pElement.offsetLeft
 y += pElement.offsetTop
 }
 pElement = pElement.offsetParent
}
document.all.myDIV.style.pixelLeft = x
document.all.myDIV.style.pixelTop = y
document.all.myDIV.style.visibility = "visible"
}
</SCRIPT>
</HEAD>
<BODY onload="setImagePosition()">
<SCRIPT LANGUAGE="JavaScript">
</SCRIPT>
<H1>The offsetParent Property</H1>
<HR>
<P>After the document loads, the script positions a small image in the upper
left corner of the second table cell.</P>
<TABLE BORDER=1 ALIGN="center">
<TR>
 <TD>This is the first cell</TD>
 <TD ID="myCell">This is the second cell.</TD>
</TR>
</TABLE>
<DIV ID="myDIV" STYLE="position:absolute; visibility:hidden; height:12;
width:12">
</DIV>
</BODY>
</HTML>

```

## outerHTML outerText

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The page generated by Listing 15-13 (IE4+/Windows only) contains an `H1` element label and a paragraph of text. The purpose is to demonstrate how the `outerHTML` and `outerText` properties differ in their intent. Two text boxes contain the same combination of text and HTML tags that replaces the element that creates the paragraph's label.

If you apply the default content of the first text box to the `outerHTML` property of the `label1` object, the `H1` element is replaced by a `SPAN` element whose `CLASS` attribute acquires a different style sheet rule defined earlier in the document. Notice that the ID of the new `SPAN` element is the same as the original `H1` element. This allows the script attached to the second button to address the object. But this second script replaces the element with the raw text (including tags). The element is now gone, and any attempt to change the `outerHTML` or `outerText` properties of the `label1` object causes an error because there is no longer a `label1` object in the document.

Use this laboratory to experiment with some other content in both text boxes.

### Listing 15-13: Using `outerHTML` and `outerText` Properties

```
<HTML>
<HEAD>
<TITLE>outerHTML and outerText Properties</TITLE>
<STYLE TYPE="text/css">
H1 {font-size:18pt; font-weight:bold; font-family:"Comic Sans MS", Arial, sans-serif}
.heading {font-size:20pt; font-weight:bold; font-family:"Arial Black", Arial, sans-serif}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">

function setGroupLabelAsText(form) {
 var content = form.textInput.value
 if (content) {
```

```

 document.all.label1.outerText = content
 }
}
function setGroupLabelAsHTML(form) {
 var content = form.HTMLInput.value
 if (content) {
 document.all.label1.outerHTML = content
 }
}
</SCRIPT>
</HEAD>

government for a redress of grievances.
</P>
</BODY>
</HTML>

```

## ownerDocument

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to explore the `ownerDocument` property in NN6. Enter the following statement into the top text box:

```
document.body.childNodes[5].ownerDocument
```

The result is a reference to the `document` object. You can use that to inspect a property of the document, as shown in the following statement you should enter into the top text box:

```
document.body.childNodes[5].ownerDocument.URL
```

This returns the `document.URL` property for the document that owns the child node.

## parentElement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

You can experiment with the `parentElement` property in The Evaluator. The document contains a `P` element named `myP`. Type each of the following statements from the left column into the upper expression evaluation text box and press Enter to see the results.

<b>Expression</b>	<b>Result</b>
<code>document.all.myP.tagName</code>	<code>P</code>
<code>document.all.myP.parentElement</code>	<code>[object]</code>
<code>document.all.myP.parentElement.tagName</code>	<code>BODY</code>
<code>document.all.myP.parentElement.parentElement</code>	<code>[object]</code>
<code>document.all.myP.parentElement.parentElement.tagName</code>	<code>HTML</code>
<code>document.all.myP.parentElement.parentElement.parentElement</code>	<code>null</code>

## parentNode

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Use The Evaluator to examine the `parentNode` property values of both an element and a non-element node. Begin with the following two statements and watch the results of each:

```
document.getElementById("myP").parentNode.tagName
document.getElementById("myP").parentElement.tagName (IE only)
```

Now examine the properties from the point of view of the first text fragment node of the `myP` paragraph element:

```
document.getElementById("myP").childNodes[0].nodeValue
document.getElementById("myP").childNodes[0].parentNode.tagName
document.getElementById("myP").childNodes[0].parentElement (IE only)
```

Notice (in IE) that the text node does not have a `parentElement` property.

## parentTextEdit

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The page resulting from Listing 15-14 contains a paragraph of Greek text and three radio buttons that select the size of a paragraph chunk: one character, one word, or one sentence. If you click anywhere within the large paragraph, the `onClick` event handler invokes the `selectChunk()` function. The function first examines which of the radio buttons is selected to determine how much of the paragraph to highlight (select) around the point at which the user clicks.

After the script employs the `parentTextEdit` property to test whether the clicked element has a valid parent capable of creating a text range, it calls upon the property again to help create the text range. From there, `TextRange` object methods

shrink the range to a single insertion point, move that point to the spot nearest the cursor location at click time, expand the selection to encompass the desired chunk, and select that bit of text.

Notice one workaround for the `TextRange` object's `expand()` method anomaly: If you specify a sentence, IE doesn't treat the beginning of a `P` element as the starting end of a sentence automatically. A camouflaged (white text color) period is appended to the end of the previous element to force the `TextRange` object to expand only to the beginning of the first sentence of the targeted `P` element.

### Listing 15-14: Using the `parentTextEdit` Property

```
<HTML>
<HEAD>
<TITLE>parentTextEdit Property</TITLE>
<STYLE TYPE="text/css">
P {cursor:hand}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function selectChunk() {
 var chunk, range
 for (var i = 0; i < document.forms[0].chunk.length; i++) {
 if (document.forms[0].chunk[i].checked) {
 chunk = document.forms[0].chunk[i].value
 break
 }
 }
 var x = window.event.clientX
 var y = window.event.clientY
 if (window.event.srcElement.parentTextEdit) {
 range = window.event.srcElement.parentTextEdit.createTextRange()
 range.collapse()
 range.moveToPoint(x, y)
 range.expand(chunk)
 range.select()
 }
}
</SCRIPT>
</HEAD>

<BODY BGCOLOR="white">
<FORM>
<P>Choose how much of the paragraph is to be selected when you click anywhere in it:

<INPUT TYPE="radio" NAME="chunk" VALUE="character" CHECKED>Character
<INPUT TYPE="radio" NAME="chunk" VALUE="word">Word
<INPUT TYPE="radio" NAME="chunk" VALUE="sentence">Sentence
```

```
.</P>
</FORM>
```

```
<P onClick="selectChunk()">
Lorem ipsum dolor sit amet, consectetur adipisicing elit, sed do eiusmod tempor
incididunt ut labore et dolore magna aliqua. Ut enim adminim veniam, quis
nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.
Duis aute irure dolor in reprehenderit involuptate velit esse cillum dolore eu
fugiat nulla pariatur. Excepteur sint occaecat cupidatat non proident, sunt in
culpa qui officia deserunt mollit anim id est laborum.
</P>
</BODY>
</HTML>
```

## previousSibling

See `nextSibling`.

## readyState

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

To witness a `readyState` property other than `complete` for standard HTML, you can try examining the property in a script that immediately follows an `<IMG>` tag:

```
...

<SCRIPT LANGUAGE="JavaScript">
alert(document.all.myImg.readyState)
</SCRIPT>
...
```

Putting this fragment into a document that is accessible across a slow network helps. If the image is not in the browser's cache, you might get the `uninitialized` or `loading` result. The former means that the `IMG` object exists, but it has not started receiving the image data from the server yet. If you reload the page, chances are that the image will load instantaneously from the cache and the `readyState` property will report `complete`.

## recordNumber

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

**Example**

You can see the `recordNumber` property in action in Listing 15-15. The data source is a small, tab-delimited file consisting of 20 records of Academy Award data. Thus, the table that displays a subset of the fields is bound to the data source object. Also bound to the data source object are three SPAN objects embedded within a paragraph near the top of the page. As the user clicks a row of data, three fields from that clicked record are placed into the bound SPAN objects.

The script part of this page is a mere single statement. When the user triggers the `onClick` event handler of the repeated TR object, the function receives as a parameter a reference to the TR object. The data store object maintains an internal copy of the data in a `recordset` object. One of the properties of this `recordset` object is the `AbsolutePosition` property, which is the integer value of the current record that the data object points to (it can point to only one row at a time, and the default row is the first row). The statement sets the `AbsolutePosition` property of the `recordset` object to the `recordNumber` property for the row that the user clicks. Because the three SPAN elements are bound to the same data source, they are immediately updated to reflect the change to the data object's internal pointer to the current record. Notice, too, that the third SPAN object is bound to one of the data source fields not shown in the table. You can reach any field of a record because the Data Source Object holds the entire data source content.

**Listing 15-15: Using the Data Binding `recordNumber` Property**

```
<HTML>
<HEAD>
<TITLE>Data Binding (recordNumber)</TITLE>
<STYLE TYPE="text/css">
.filmTitle {font-style:italic}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
// set recordset pointer to the record clicked on in the table.
function setRecNum(row) {
 document.oscars.recordset.AbsolutePosition = row.recordNumber
}
</SCRIPT>
```

```

</HEAD>
<BODY>
<P>Academy Awards 1978-1997 (Click on a table row to extract data from
one record.)</P>
<P>The award for Best Actor of
 went to
 for his outstanding achievement in the film
.</P>
<TABLE BORDER=1 DATASRC="#oscars" ALIGN="center">
<THEAD STYLE="background-color:yellow; text-align:center">
<TR><TD>Year</TD>
<TD>Film</TD>
<TD>Director</TD>
<TD>Actress</TD>
<TD>Actor</TD>
</TR>
</THEAD>
<TR ID=repeatableRow onClick="setRecNum(this)">
<TD><DIV ID="col1" DATAFLD="Year"></DIV></TD>

<OBJECT ID="oscars" CLASSID="clsid:333C7BC4-460F-11D0-BC04-0080C7055A83">
<PARAM NAME="DataURL" VALUE="Academy Awards.txt">
<PARAM NAME="UseHeader" VALUE="True">
<PARAM NAME="FieldDelim" VALUE="	">
</OBJECT>
</BODY>
</HTML>

```

## runtimeStyle

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to compare the properties of the `runtimeStyle` and `style` objects of an element. For example, an unmodified copy of The Evaluator contains an EM element whose ID is "myEM". Enter both

```
document.all.myEM.style.color
```

and

```
document.all.myEM.runtimeStyle.color
```

into the top text field in turn. Initially, both values are empty. Now assign a color to the `style` property via the upper text box:

```
document.all.myEM.style.color = "red"
```

If you now type the two earlier statements into the upper box, you can see that the `style` object reflects the change, while the `runtimeStyle` object still holds onto its original (empty) value.

## scopeName

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

If you have a sample document that contains XML and a namespace spec, you can use `document.write()` or `alert()` methods to view the value of the `scopeName` property. The syntax is

```
document.all.elementID.scopeName
```

## scrollHeight scrollWidth

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with these two properties of the `TEXTAREA` object, which displays the output of evaluations and property listings.

To begin, enter the following into the bottom one-line text field to list the properties of the `body` object:

```
document.body
```

This displays a long list of properties for the `body` object. Now enter the following property expression in the top one-line text field to see the `scrollHeight` property of the output TEXTAREA when it holds the dozens of lines of property listings:

```
document.all.output.scrollHeight
```

The result, some number probably in the hundreds, is now displayed in the output TEXTAREA. This means that you can scroll the content of the `output` element vertically to reveal that number of pixels. Click the Evaluate button once more. The result, 13 or 14, is a measure of the `scrollHeight` property of the TEXTAREA that had only the previous result in it. The scrollable height of that content was only 13 or 14 pixels, the height of the font in the TEXTAREA. The `scrollWidth` property of the output TEXTAREA is fixed by the width assigned to the element's `COLS` attribute (as calculated by the browser to determine how wide to make the textarea on the page).

## scrollLeft scrollTop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with these two properties of the TEXTAREA object, which displays the output of evaluations and property listings. To begin, enter the following into the bottom one-line text field to list the properties of the `body` object:

```
document.body
```

This displays a long list of properties for the `body` object. Use the TEXTAREA's scrollbar to page down a couple of times. Now enter the following property expression in the top one-line text field to see the `scrollTop` property of the output TEXTAREA after you scroll:

```
document.all.output.scrollTop
```

The result, some number, is now displayed in the output TEXTAREA. This means that the content of the `output` element was scrolled vertically. Click the Evaluate button once more. The result, 0, is a measure of the `scrollTop` property of the TEXTAREA that had only the previous result in it. There wasn't enough content in the TEXTAREA to scroll, so the content was not scrolled at all. The `scrollTop` property, therefore, is zero. The `scrollLeft` property of the output is always zero because the TEXTAREA element is set to wrap any text that overflows the width of the element. No horizontal scrollbar appears in this case, and the `scrollLeft` property never changes.

## sourceIndex

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

While the operation of this property is straightforward, the sequence of elements exposed by the `document.all` property may not be. To that end, you can use The Evaluator (Chapter 13) to experiment in IE4+ with the values that the `sourceIndex` property returns to see how the index values of the `document.all` collection follow the source code.

To begin, reload The Evaluator. Enter the following statement in the top text box to set a preinitialized global variable:

```
a = 0
```

When you evaluate this expression, a zero should appear in the Results box. Next, enter the following statement into the top text box:

```
document.all[a].tagName + " [" + a++ + "]"
```

There are a lot of plus signs in this statement, so be sure you enter it correctly. As you successively evaluate this statement (repeatedly click the Evaluate button), the global variable (`a`) is incremented, thus enabling you to “walk through” the elements in source code order. The `sourceIndex` value for each HTML tag appears in square brackets in the Results box. You generally begin with the following sequence:

```
HTML [0]
HEAD [1]
TITLE [2]
```

You can continue until there are no more elements, at which point an error message appears because the value of `a` exceeds the number of elements in the `document.all` array. Compare your findings against the HTML source code view of The Evaluator.

## style

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Most of the action with the `style` property has to do with the `style` object's properties, so you can use The Evaluator here to simply explore the lists of `style` object properties available on as many DHTML-compatible browsers as you have running. To begin, enter the following statement into the lower, one-line text box to inspect the `style` property for the `document.body` object:

```
document.body.style
```

Now inspect the `style` property of the table element that is part of the original version of The Evaluator. Enter the following statement into the lower text box:

```
document.getElementById("myTable").style
```

In both cases, the values assigned to the `style` object's properties are quite limited by default.

## tabIndex

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The HTML and scripting in Listing 15-16 demonstrate not only the way you can modify the tabbing behavior of a form on the fly, but also how to force form elements out of the tabbing sequence entirely in IE. In this page, the upper form

(named `lab`) contains four elements. Scripts invoked by buttons in the lower form control the tabbing sequence. Notice that the `TABINDEX` attributes of all lower form elements are set to `-1`, which means that these control buttons are not part of the tabbing sequence in IE.

When you load the page, the default tabbing order for the `lab` form control elements (default setting of zero) takes charge. If you start pressing the Tab key, the precise results at first depend on the browser you use. In IE, the Address field is first selected; next the Tab sequence gives focus to the window (or frame, if this page were in a frameset); finally the tabbing reaches the `lab` form. Continue pressing the Tab key and watch how the browser assigns focus to each of the element types. In NN6, however, you must click anywhere on the content to get the Tab key to start working on form controls.

The sample script inverts the tabbing sequence with the help of a `for` loop that initializes two variables that work in opposite directions as the looping progresses. This gives the last element the lowest `tabIndex` value. The `skip2()` function simply sets the `tabIndex` property of the second text box to `-1`, removing it from the tabbing entirely (IE only). Notice, however, that you can click in the field and still enter text. (See the `disabled` property earlier in this chapter to see how to prevent field editing.) NN6 does not provide a `tabIndex` property setting that forces the browser to skip over a form control. You should disable the control instead.

### Listing 15-16: Controlling the `tabIndex` Property

```
<HTML>
<HEAD>
<TITLE>tabIndex Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function invert() {
 var form = document.lab
 for (var i = 0, j = form.elements.length; i < form.elements.length;
i++, j--) {
 form.elements[i].tabIndex = j
 }
}

function skip2() {
 document.lab.text2.tabIndex = -1
}

function resetTab() {
 var form = document.lab
 for (var i = 0; i < form.elements.length; i++) {
 form.elements[i].tabIndex = 0
 }
}
```

```

}
</SCRIPT>
</HEAD>

<BODY>
<H1>tabIndex Property Lab</H1>
<HR>
<FORM NAME="lab">
Text box no. 1: <INPUT TYPE="text" NAME="text1">

Text box no. 2: <INPUT TYPE="text" NAME="text2">

<INPUT TYPE="button" VALUE="A Button">

<INPUT TYPE="checkbox">And a checkbox
</FORM>
<HR>
<FORM NAME="control">
<INPUT TYPE="button" VALUE="Invert Tabbing Order" TABINDEX=-1
onClick="invert()">

<INPUT TYPE="button" VALUE="Skip Text box no. 2 (IE Only)" TABINDEX=-1
onClick="skip2()">

<INPUT TYPE="button" VALUE="Reset to Normal Order" TABINDEX=-1
onClick="resetTab()">
</FORM>
</BODY>
</HTML>

```

The final function, `resetTab()`, sets the `tabIndex` property value to zero for all `lab` form elements. This restores the default order; but in IE5.5/Windows, you may experience buggy behavior that prevents you from tabbing to items after you reset them. Only the reloading of the page provides a complete restoration of default behavior.

## tagName

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

You can see the `tagName` property in action for the example associated with the `sourceIndex` property discussed earlier. In that example, the `tagName` property is read from a sequence of objects in source code order.

## tagUrn

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

**Example**

If you have a sample document that contains XML and a Namespace spec, you can use `document.write()` or `alert()` methods to view the value of the `tagUrn` property. The syntax is

```
document.all.elementID.tagUrn
```

## title

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

You can see how dynamic a tooltip is in Listing 15-17. A simple paragraph element has its `TITLE` attribute set to "First Time!", which is what the tooltip displays if you roll the pointer atop the paragraph and pause after the page loads. But an `onMouseOver` event handler for that element increments a global variable counter in the script, and the `title` property of the paragraph object is modified with each mouseover action. The `count` value is made part of a string assigned to the `title` property. Notice that there is not a live connection between the `title` property and the variable; instead, the new value explicitly sets the `title` property.

**Listing 15-17: Controlling the title Property**

```
<HTML>
<HEAD>
<TITLE>title Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// global counting variable
```

```

var count = 0

function setToolTip(elem) {
 elem.title = "You have previously rolled atop this paragraph " +
 count + " time(s)."
}

function incrementCount(elem) {
 count++
 setToolTip(elem)
}
</SCRIPT>

</HEAD>
<BODY>
<H1>title Property Lab</H1>
<HR>
<P ID="myP" TITLE="First Time!" onMouseOver="incrementCount(this)">
Roll the mouse over this paragraph a few times.

Then pause atop it to view the tooltip.</P>
</BODY>
</HTML>

```

## uniqueID

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-18 demonstrates the recommended syntax for obtaining and applying a browser-generated identifier for an object. After you enter some text into the text box and click the button, the `addRow()` function appends a row to the table. The left column displays the identifier generated via the table row object's `uniqueID` property. IE5+ generates identifiers in the format "ms\_\_id*n*", where *n* is an integer starting with zero for the current browser session. Because the `addRow()` function assigns `uniqueID` values to the row and the cells in each row, the integer for each row is three greater than the previous one. There is no guarantee that future generations of the browser will follow this format, so do not rely on the format or sequence in your scripts.

### Listing 15-18: Using the uniqueID Property

```

<HTML>
<HEAD>
<TITLE>Inserting an IE5+/Windows Table Row</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function addRow(item1) {
 if (item1) {
 // assign long reference to shorter var name
 var theTable = document.all.myTable
 // append new row to the end of the table
 var newRow = theTable.insertRow(theTable.rows.length)
 // give the row its own ID
 newRow.id = newRow.uniqueID

 // declare cell variable
 var newCell

 // an inserted row has no cells, so insert the cells
 newCell = newRow.insertCell(0)
 // give this cell its own id
 newCell.id = newCell.uniqueID
 // display the row's id as the cell text
 newCell.innerHTML = newRow.id
 newCell.bgColor = "yellow"
 // reuse cell var for second cell insertion
 newCell = newRow.insertCell(1)
 newCell.id = newCell.uniqueID
 newCell.innerHTML = item1
 }
}
</SCRIPT>
</HEAD>

<BODY>
<TABLE ID="myTable" BORDER=1>
<TR>
<TH>Row ID</TH>
<TH>Data</TH>
</TR>

<TR ID="firstDataRow">
<TD>firstDataRow
<TD>Fred
</TR>
<TR ID="secondDataRow">
<TD>secondDataRow
<TD>Jane
</TR>
</TABLE>
<HR>

```

```

<FORM>
Enter text to be added to the table:

<INPUT TYPE="text" NAME="input" SIZE=25>

<INPUT TYPE='button' VALUE='Insert Row' onClick='addRow(this.form.input.value)'\>
</FORM>
</BODY>
</HTML>

```

## Methods

`addBehavior("URL")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-19a is the JavaScript code for an external component named `makeHot.htc`. Its purpose is to turn the `color` style property of an object to either a default color ("red") or any other color that is passed to the component. For details on the syntax of the `<PUBLIC>` tags, see Chapter 48. The code presented here helps you see how the page and scripts in Listing 15-19b work.

#### Listing 15-19a: The `makeHot.htc` Behavior Component

```

<PUBLIC:ATTACH EVENT="onmousedown" ONEVENT="makeHot()" />
<PUBLIC:ATTACH EVENT="onmouseup" ONEVENT="makeNormal()" />
<PUBLIC:PROPERTY NAME="hotColor" />
<PUBLIC:METHOD NAME="setHotColor" />
<SCRIPT LANGUAGE="JScript">
var oldColor
var hotColor = "red"

function setHotColor(color) {
 hotColor = color
}

function makeHot() {
 if (event.srcElement == element) {

```

*Continued*

**Listing 15-19a (continued)**

```

 oldColor = style.color
 runtimeStyle.color = hotColor
 }
}

function makeNormal() {
 if (event.srcElement == element) {
 runtimeStyle.color = oldColor
 }
}
</SCRIPT>

```

The object to which the component is attached is a simple paragraph object, shown in Listing 15-19b. When the page loads, the behavior is not attached so clicking the paragraph text has no effect.

When you turn on the behavior by invoking the `turnOn()` function, the `addBehavior()` method attaches the code of the `makeHot.htc` component to the `myP` object. At this point, the `myP` object has one more property, one more method, and two more event handlers that are written to be made public by the component's code. If you want the behavior to apply to more than one paragraph in the document, you have to invoke the `addBehavior()` method for each paragraph object.

After the behavior file is instructed to start loading, the `setInitialColor()` function is called to set the new color property of the paragraph to the user's choice from the SELECT list. But this can happen only if the component is fully loaded. Therefore, the function checks the `readyState` property of `myP` for completeness before invoking the component's function. If IE is still loading the component, the function is invoked again in 500 milliseconds.

As long as the behavior is loaded, you can change the color used to turn the paragraph "hot." The function first ensures that the component is loaded by checking that the object has the new color property. If it does, then (as a demonstration of how to expose and invoke a component method) the method of the component is invoked. You can also simply set the property value.

**Listing 15-19b: Using `addBehavior()` and `removeBehavior()`**

```

<HTML>
<HEAD>
<TITLE>addBehavior() and removeBehavior() Methods</TITLE>

```

```

<SCRIPT LANGUAGE="JavaScript">
var myPBehaviorID

function turnOn() {
 myPBehaviorID = document.all.myP.addBehavior("makeHot.htc")
 setInitialColor()
}

function setInitialColor() {
 if (document.all.myP.readyState == "complete") {
 var select = document.forms[0].colorChoice
 var color = select.options[select.selectedIndex].value
 document.all.myP.setHotColor(color)
 } else {
 setTimeout("setInitialColor()", 500)
 }
}

function turnOff() {
 document.all.myP.removeBehavior(myPBehaviorID)
}

function setColor(select, color) {
 if (document.all.myP.hotColor) {
 document.all.myP.setHotColor(color)
 } else {
 alert("This feature is not available. Turn on the Behavior first.")
 select.selectedIndex = 0
 }
}

function showBehaviorCount() {
 var num = document.all.myP.behaviorUrns.length
 var msg = "The myP element has " + num + " behavior(s). "
 if (num > 0) {
 msg += "Name(s): \r\n"
 for (var i = 0; i < num; i++) {
 msg += document.all.myP.behaviorUrns[i] + "\r\n"
 }
 }
 alert(msg)
}
</SCRIPT>
</HEAD>
<BODY>
<H1>addBehavior() and removeBehavior() Method Lab</H1>
<HR>
<P ID="myP">This is a sample paragraph. After turning on the behavior,
it will turn your selected color when you mouse down anywhere in this
paragraph.</P>
<FORM>

```

*Continued*

## Listing 15-19b (continued)

```

<INPUT TYPE="button" VALUE="Switch On Behavior" onClick="turnOn()">
Choose a 'hot' color:
<SELECT NAME="colorChoice" onChange="setColor(this, this.value)">
<OPTION VALUE="red">red
<OPTION VALUE="blue">blue
<OPTION VALUE="cyan">cyan
</SELECT>

<INPUT TYPE="button" VALUE="Switch Off Behavior" onClick="turnOff()">
<P><INPUT TYPE="button" VALUE="Count the URNs"
onClick="showBehaviorCount()"></P>
</BODY>
</HTML>

```

To turn off the behavior, the `removeBehavior()` method is invoked. Notice that the `removeBehavior()` method is associated with the `myP` object, and the parameter is the ID of the behavior added earlier. If you associate multiple behaviors with an object, you can remove one without disturbing the others because each has its own unique ID.

```

addEventListener("eventType", listenerFunc,
useCapture)
removeEventListener("eventType",
listenerFunc, useCapture)

```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

**Example**

Listing 15-20 provides a compact workbench to explore and experiment with the basic W3C DOM event model. When the page loads, no event listeners are registered with the browser (except for the control buttons, of course). But you can add an event listener for a `click` event in bubble and/or capture mode to the `BODY` element or the `P` element that surrounds the `SPAN` holding the line of text. If you add an event listener and click the text, you see a readout of the element processing the event and information indicating whether the event phase is bubbling (3) or capture (1). With all event listeners engaged, notice the sequence of events being processed. Remove listeners one at a time to see the effect on event processing.

**Note**

Listing 15-20 includes code for event capture that does not operate in NN6. Event capture facilities should work in a future version of the browser.

**appendChild(*elementObject*)**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

## Example

Scripts in Listing 15-21 demonstrate how the three major child-related methods work in IE5+ and NN6. The page includes a simple, two-item list. A form enables you to add items to the end of the list or replace the last item with a different entry.

The `append()` function creates a new LI element and then uses the `appendChild()` method to attach the text box text as the displayed text for the item. The nested expression, `document.createTextNode(form.input.value)`, evaluates to a legitimate node that is appended to the new LI item. All of this occurs before the new LI item is added to the document. In the final statement of the function, `appendChild()` is invoked from the vantage point of the UL element — thus adding the LI element as a child node of the UL element.

Invoking the `replaceChild()` method in the `replace()` function utilizes some of the same code. The main difference is that the `replaceChild()` method requires a second parameter: a reference to the child element to be replaced. This demonstration replaces the final child node of the UL list, so the function takes advantage of the `lastChild` property of all elements to get a reference to that final nested child. That reference becomes the second parameter to `replaceChild()`.

### Listing 15-21: Various Child Methods

```
<HTML>
<HEAD>
<TITLE>appendChild(), removeChild(), and replaceChild() Methods</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function append(form) {
 if (form.input.value) {
 var newItem = document.createElement("LI")
 newItem.appendChild(document.createTextNode(form.input.value))
 document.getElementById("myUL").appendChild(newItem)
 }
}

function replace(form) {
 if (form.input.value) {
 var newItem = document.createElement("LI")
 var lastChild = document.getElementById("myUL").lastChild
 newItem.appendChild(document.createTextNode(form.input.value))
 document.getElementById("myUL").replaceChild(newItem, lastChild)
 }
}

function restore() {
 var oneChild
 var mainObj = document.getElementById("myUL")
```

*Continued*

## Listing 15-21 (continued)

```

 while (mainObj.childNodes.length > 2) {
 oneChild = mainObj.lastChild
 mainObj.removeChild(oneChild)
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Child Methods</H1>
<HR>
Here is a list of items:
<UL ID="myUL">First Item
Second Item

<FORM>
Enter some text to add/replace in the list:
<INPUT TYPE="text" NAME="input" SIZE=30>

<INPUT TYPE="button" VALUE="Append to List" onClick="append(this.form)">
<INPUT TYPE="button" VALUE="Replace Final Item" onClick="replace(this.form)">
<INPUT TYPE="button" VALUE="Restore List" onClick="restore()">
</BODY>
</HTML>

```

The final part of the demonstration uses the `removeChild()` method to peel away all children of the UL element until just the two original items are left standing. Again, the `lastChild` property comes in handy as the `restore()` function keeps removing the last child until only two remain. Upon restoring the list, IE5/Mac fails to render the list bullets; but in the browser's object model, the UL element still exists.

`applyElement(elementObject[, type])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

**Example**

To help you visualize the impact of the `applyElement()` method with its different parameter settings, Listing 15-22 enables you to apply a new element (an EM element) to a SPAN element inside a paragraph. At any time, you can view the HTML of the entire P element to see where the EM element is applied as well as its impact on the element containment hierarchy for the paragraph.

After you load the page, inspect the HTML for the paragraph before doing anything else. Notice the SPAN element and its nested FONT element, both of which surround the one-word content. If you apply the EM element inside the SPAN element (click the middle button), the SPAN element's first (and only) child element becomes the EM element; the FONT element is now a child of the new EM element.

### Listing 15-22: Using the applyElement() Method

```
<HTML>
<HEAD>
<TITLE>applyElement() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function applyOutside() {
 var newItem = document.createElement("EM")
 newItem.id = newItem.uniqueID
 document.all.mySpan.applyElement(newItem)
}

function applyInside() {
 var newItem = document.createElement("EM")
 newItem.id = newItem.uniqueID
 document.all.mySpan.applyElement(newItem, "inside")
}

function showHTML() {
 alert(document.all.myP.outerHTML)
}
</SCRIPT>
</HEAD>
<BODY>
<H1>applyElement() Method</H1>
<HR>
<P ID="myP">A simple paragraph with a
special word in it.</P>
<FORM>
<INPUT TYPE="button" VALUE="Apply Outside" onClick="applyOutside()">
<INPUT TYPE="button" VALUE="Apply Inside" onClick="applyInside()">
<INPUT TYPE="button" VALUE="Show <P> HTML..." onClick="showHTML()">

<INPUT TYPE="button" VALUE="Restore Paragraph" onClick="location.reload()">
</BODY>
</HTML>
```

The visible results of applying the EM element inside and outside the SPAN element in this case are the same. But you can see from the HTML results that each element impacts the element hierarchy quite differently.

```
attachEvent("eventName", functionRef)
detachEvent("eventName", functionRef)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to create an anonymous function that is called in response to an `onmousedown` event of the first paragraph on the page. Begin by assigning the anonymous function to global variable `a` (already initialized in The Evaluator) in the upper text box:

```
a = new Function("alert('Function created at " + (new Date()) + "')")
```

The quote marks and parentheses can get jumbled easily, so enter this expression carefully. When you enter the expression successfully, the Results box shows the function's text. Now assign this function to the `onmousedown` event of the `myP` element by entering the following statement into the upper text box:

```
document.all.myP.attachEvent("onmousedown", a)
```

The Results box displays `true` when successful. If you mouse down on the first paragraph, an alert box displays the date and time that the anonymous function was created (when the new `Date()` expression was evaluated).

Now, disconnect the event relationship from the object by entering the following statement into the upper text box:

```
document.all.myP.detachEvent("onmousedown", a)
```

```
blur()
focus()
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

To show how both the `window.focus()` method and its opposite (`window.blur()`) operate, Listing 15-23 for NN3+ and IE4+ creates a two-window environment. From each window, you can bring the other window to the front. The main window uses the object returned by `window.open()` to assemble the reference to the new window. In the subwindow (whose content is created entirely on the fly by JavaScript), `self.opener` is summoned to refer to the original window, while `self.blur()` operates on the subwindow itself (except for the buggy behavior of NN6 noted earlier). Blurring one window and focusing on another window yields the same result of sending the window to the back of the pile.

### Listing 15-23: The `window.focus()` and `window.blur()` Methods

```
<HTML>
<HEAD>
<TITLE>Window Focus() and Blur()</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
// declare global variable name
var newWindow = null
function makeNewWindow() {
 // check if window already exists
 if (!newWindow || newWindow.closed) {
 // store new window object in global variable
 newWindow = window.open("", "", "width=250,height=250")
 // pause briefly to let IE3 window finish opening
 setTimeout("fillWindow()",100)
 } else {
 // window already exists, so bring it forward
 newWindow.focus()
 }
}
// assemble new content and write to subwindow
function fillWindow() {
 var newContent = "<HTML><HEAD><TITLE>Another Subwindow</TITLE></HEAD>"
 newContent += "<BODY bgColor='salmon'>"
 newContent += "<H1>A Salmon-Colored Subwindow.</H1>"
 newContent += "<FORM><INPUT TYPE='button' VALUE='Bring Main to Front'
onClick='self.opener.focus()'>"
 // the following button doesn't work in NN6
 newContent += "<FORM><INPUT TYPE='button' VALUE='Put Me in Back'
onClick='self.blur()'>"
 newContent += "</FORM></BODY></HTML>"
 // write HTML to new window document
```

*Continued*

**Listing 15-23 (continued)**

```

 newWindow.document.write(newContent)
 newWindow.document.close()
 }
</SCRIPT>
</HEAD>
<BODY>
<H1>Window focus() and blur() Methods</H1>
<HR>
<FORM>
<INPUT TYPE="button" NAME="newOne" VALUE="Show New Window"
onClick="makeNewWindow()">
</FORM>
</BODY>
</HTML>

```

A key ingredient to the success of the `makeNewWindow()` function in Listing 15-23 is the first conditional expression. Because `newWind` is initialized as a `null` value when the page loads, that is its value the first time through the function. But after you open the subwindow the first time, `newWind` is assigned a value (the subwindow object) that remains intact even if the user closes the window. Thus, the value doesn't revert to `null` by itself. To catch the possibility that the user has closed the window, the conditional expression also sees if the window is closed. If it is, a new subwindow is generated, and that new window's reference value is reassigned to the `newWind` variable. On the other hand, if the window reference exists and the window is not closed, the `focus()` method brings that subwindow to the front.

You can see the `focus()` method for a text object in action in Chapter 25's description of the `select()` method for text objects.

## clearAttributes()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to examine the attributes of an element before and after you apply `clearAttributes()`. To begin, display the HTML for the table element on the page by entering the following statement into the upper text field:

```
elementObject.clearAttributes()
```

```
myTable.outerHTML
```

Notice the attributes associated with the `<TABLE>` tag. Look at the rendered table to see how attributes such as `BORDER` and `WIDTH` affect the display of the table. Now, enter the following statement in the top text box to remove all removable attributes from this element:

```
myTable.clearAttributes()
```

First, look at the table. The border is gone, and the table is rendered only as wide as is necessary to display the content with no cell padding. Lastly, view the results of the `clearAttributes()` method in the `outerHTML` of the table again:

```
myTable.outerHTML
```

The source code file has not changed, but the object model in the browser's memory reflects the changes you made.

## click()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `click()` method. The page includes various types of buttons at the bottom. You can “click” the checkbox, for example, by entering the following statement in the topmost text field:

```
document.myForm2.myCheckbox.click()
```

If you use a recent browser version, you most likely can see the checkbox change states between checked and unchecked each time you execute the statement.

## cloneNode(*deepBoolean*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Use The Evaluator (Chapter 13) to clone, rename, and append an element found in The Evaluator's source code. Begin by cloning the paragraph element named `myP` along with all of its content. Enter the following statement into the topmost text field:

```
a = document.getElementById("myP").cloneNode(true)
```

The variable `a` now holds the clone of the original node, so you can change its `ID` attribute at this point by entering the following statement:

```
a.setAttribute("ID", "Dolly")
```

If you want to see the properties of the cloned node, enter `a` into the lower text field. The precise listing of properties you see depends on whether you use NN or IE; in either case, you should be able to locate the `id` property, whose value is now `Dolly`.

As a final step, append this newly named node to the end of the `body` element by entering the following statement into the topmost text field:

```
document.body.appendChild(a)
```

You can now scroll down to the bottom of the page and see a duplicate of the content. But because the two nodes have different `ID` attributes, they cannot confuse scripts that need to address one or the other.

## componentFromPoint(x,y)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

You can experiment with this method in the code supplied with Listing 15-24. As presented, the method is associated with a `TEXTAREA` object that is specifically sized to display both vertical and horizontal scrollbars. As you click various areas of the `TEXTAREA` and the rest of the page, the status bar displays information about the location of the event with the help of the `componentFromPoint()` method.

The script utilizes a combination of the `event.srcElement` property and the `componentFromPoint()` method to help you distinguish how you can use each one for different types of event processing. The `srcElement` property is used initially as a filter to decide whether the status bar will reveal further processing about the `TEXTAREA` element's event details.

The `onMouseDown` event handler in the `BODY` element triggers all event processing. IE events bubble up the hierarchy (and no events are cancelled in this page), so all `mouseDown` events eventually reach the `BODY` element. Then, the `whereInWorld()` function can compare each `mouseDown` event from any element against the `textarea`'s geography.

### Listing 15-24: Using the `componentFromPoint()` Method

```
<HTML>
<HEAD>
<TITLE>componentFromPoint() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function whereInWorld(elem) {
 var x = event.clientX
 var y = event.clientY
 var component = document.all.myTextarea.componentFromPoint(x,y)
 if (window.event.srcElement == document.all.myTextarea) {
 if (component == "") {
 status = "mouseDown event occurred inside the element"
 } else {
 status = "mouseDown occurred on the element\'s " + component
 }
 } else {
 status = "mouseDown occurred " + component + " of the element"
 }
}
</SCRIPT>
</HEAD>
<BODY onMouseDown="whereInWorld()">
<H1>componentFromPoint() Method</H1>
<HR>
<P>Tracking the mouseDown event relative to the textarea object. View results in
status bar.</P>
<FORM>
<TEXTAREA NAME="myTextarea" WRAP="off" COLS=12 ROWS=4>
This is Line 1
This is Line 2
This is Line 3
This is Line 4
This is Line 5
This is Line 6
</TEXTAREA>
</FORM>
</BODY>
</HTML>
```

## contains(*elementObjectReference*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Using The Evaluator (Chapter 13), see how the `contains()` method responds to the object combinations in each of the following statements as you enter them into the upper text box:

```
document.body.contains(document.all.myP)
document.all.myP.contains(document.all.item("myEM"))
document.all.myEM.contains(document.all.myEM)
document.all.myEM.contains(document.all.myP)
```

Feel free to test other object combinations within this page.

## detachEvent()

See `attachEvent()`.

## dispatchEvent(*eventObject*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Listing 15-25 demonstrates the `dispatchEvent()` method as defined in the W3C DOM Level 2. The behavior is identical to that of Listing 15-26, which demonstrates the IE5.5 equivalent: `fireEvent()`. This example does not perform all intended actions in the first release of NN6 because the browser does not fully implement the `document.createEvent()` method. The example is designed to operate more completely in a future version that supports event generation.

**Listing 15-25: Using the `dispatchEvent()` Method**

```
<HTML>
<HEAD>
<STYLE TYPE="text/css">
#mySPAN {font-style:italic}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
// assemble a couple event object properties
function getEventProps(evt) {
 var msg = ""
 var elem = evt.target
 msg += "event.target.nodeName: " + elem.nodeName + "\n"
 msg += "event.target.parentNode: " + elem.parentNode.id + "\n"
 msg += "event button: " + evt.button
 return msg
}

// onClick event handlers for body, myP, and mySPAN
function bodyClick(evt) {
 var msg = "Click event processed in BODY\n\n"
 msg += getEventProps(evt)
 alert(msg)
 checkCancelBubble(evt)
}
function pClick(evt) {
 var msg = "Click event processed in P\n\n"
 msg += getEventProps(evt)
 alert(msg)
 checkCancelBubble(evt)
}
function spanClick(evt) {
 var msg = "Click event processed in SPAN\n\n"
 msg += getEventProps(evt)
 alert(msg)
 checkCancelBubble(evt)
}

// cancel event bubbling if check box is checked
function checkCancelBubble(evt) {
 if (document.controls.bubble0n.checked) {
 evt.stopPropagation()
 }
}

// assign onClick event handlers to three elements
function init() {

</HTML>

```

`fireEvent("eventType" [, eventObjectRef])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

## Example

The small laboratory of Listing 15-26 enables you to explore the possibilities of the IE5.5 `fireEvent()` method while reinforcing event bubbling concepts in IE. Three nested element objects are assigned separate `onClick` event handlers (via the `init()` function invoked after the page loads — although you can also set these event handlers via `onClick` attributes in the tags). Each handler displays an alert whose content reveals which object's event handler was triggered and the tag name and ID of the object that received the event. The default behavior of the page is to allow event bubbling, but a checkbox enables you to turn off bubbling.

After you load the page, click the italic segment (a nested SPAN element) to receive a series of three alert boxes. The first advises you that the SPAN element's `onClick` event handler is processing the event and that the SPAN element (whose ID is `mySPAN`) is, indeed, the source element of the event. Because event bubbling is enabled by default, the event bubbles upward to the SPAN element's next outermost container: the `myP` paragraph element. (However, `mySPAN` is still the source element.) Finally, the event reaches the BODY element. If you click in the H1 element at the top of the page, the event is not processed until it reaches the BODY element — although the H1 element is the source element because that's what you clicked. In all cases, when you explicitly click something to generate the `onClick` event, the event's `button` property shows zero to signify the primary mouse button in IE.

Now onto the real purpose of this example: the `fireEvent()` method. Three buttons enable you to direct a click event to each of the three elements that have event handlers defined for them. The events fired this way are artificial, generated via the `createEventObject()` method. For demonstration purposes, the `button` property of these scripted events is set to 3. This property value is assigned to the `event` object that eventually gets directed to an element. With event bubbling left on, the events sent via `fireEvent()` behave just like the physical clicks on the elements. Similarly, if you disable event bubbling, the first event handler to process the event cancels bubbling, and no further processing of that event occurs. Notice that event bubbling is cancelled within the event handlers that process the event. To prevent the clicks of the checkbox and action buttons from triggering the BODY element's `onClick` event handlers, event bubbling is turned off for the buttons right away.

### Listing 15-26: Using the `fireEvent()` Method

```
<HTML>
<HEAD>
<STYLE TYPE="text/css">
#mySPAN {font-style:italic}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
// assemble a couple event object properties
```

*Continued*

`elementObject.fireEvent()`

## Listing 15-26 (continued)

```
function getEventProps() {
 var msg = ""
 var elem = event.srcElement
 msg += "event.srcElement.tagName: " + elem.tagName + "\n"
 msg += "event.srcElement.id: " + elem.id + "\n"
 msg += "event.button: " + event.button
 return msg
}

// onClick event handlers for body, myP, and mySPAN
function bodyClick() {
 var msg = "Click event processed in BODY\n\n"
 msg += getEventProps()
 alert(msg)
 checkCancelBubble()
}
function pClick() {
 var msg = "Click event processed in P\n\n"
 msg += getEventProps()
 alert(msg)
 checkCancelBubble()
}
function spanClick() {

<P><INPUT TYPE="button" VALUE="Fire Click Event on myP"
onClick="doFire('myP')"></P>
<P><INPUT TYPE="button" VALUE="Fire Click Event on mySPAN"
onClick="doFire('mySPAN')"></P>
</FORM>
</BODY>
</HTML>

```

## focus()

See `blur()`.

## getAdjacentText("position")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to examine all four adjacent text possibilities for the `myP` and nested `myEM` elements in that document. Enter each of the following statements into the upper text box, and view the results:

```

document.all.myP.getAdjacentText("beforeBegin")
document.all.myP.getAdjacentText("afterBegin")
document.all.myP.getAdjacentText("beforeEnd")
document.all.myP.getAdjacentText("afterEnd")

```

The first and last statements return empty strings because the `myP` element has no text fragments surrounding it. The `afterBegin` version returns the text fragment of the `myP` element up to, but not including, the EM element nested inside. The `beforeEnd` string picks up after the end of the nested EM element and returns all text to the end of `myP`.

Now, see what happens with the nested `myEM` element:

```
document.all.myEM.getAdjacentText("beforeBegin")
document.all.myEM.getAdjacentText("afterBegin")
document.all.myEM.getAdjacentText("beforeEnd")
document.all.myEM.getAdjacentText("afterEnd")
```

Because this element has no nested elements, the `afterBegin` and `beforeEnd` strings are identical: the same value as the `innerText` property of the element.

`getAttribute("attributeName" [, caseSensitivity])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `getAttribute()` method for the elements in the page. For IE4, use the `document.all` notation. IE5 and NN6 understand the W3C standard `getElementById()` method of addressing an element. You can enter the following sample statements into the top text box to view attribute values.

IE4:

```
document.all.myTable.getAttribute("width")
document.all.myTable.getAttribute("border")
```

IE5/NN6:

```
document.getElementById("myTable").getAttribute("width")
document.getElementById("myTable").getAttribute("border")
```

## getAttributeNode("attributeName")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

### Example

Use The Evaluator (Chapter 13) to explore the `getAttributeNode()` method in NN6. The Results TEXTAREA element provides several attributes to check out. Because the method returns an object, enter the following statements into the bottom text field so you can view the properties of the attribute node object returned by the method:

```
document.getElementById("output").getAttributeNode("COLS")
document.getElementById("output").getAttributeNode("ROWS")
document.getElementById("output").getAttributeNode("wrap")
document.getElementById("output").getAttributeNode("style")
```

All (except the last) statements display a list of properties for each attribute node object. The last statement, however, returns nothing because the `STYLE` attribute is not specified for the element.

## getBoundingClientRect()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

### Example

Listing 15-27 employs both the `getBoundingClientRect()` and `getClientRects()` methods in a demonstration of how they differ. A set of elements are grouped within a `SPAN` element named `main`. The group consists of two paragraphs and an unordered list.

Two controls enable you to set the position of an underlying highlight rectangle to any line of your choice. A checkbox enables you to set whether the highlight rectangle should be only as wide as the line or the full width of the bounding rectangle for the entire `SPAN` element.

All the code is located in the `hilite()` function. The `SELECT` and `checkbox` elements invoke this function. Early in the function, the `getClientRects()` method is

invoked for the `main` element to capture a snapshot of all `TextRectangle` objects for the entire element. This array comes in handy when the script needs to get the coordinates of a rectangle for a single line, as chosen in the `SELECT` element.

Whenever the user chooses a number from the `SELECT` list and the value is less than the total number of `TextRectangle` objects in `clientRecls`, the function begins calculating the size and location of the underlying yellow highlighter. When the `Full Width` checkbox is checked, the left and right coordinates are obtained from the `getBoundingClientRect()` method because the entire `SPAN` element's rectangle is the space you're interested in; otherwise, you pull the left and right properties from the chosen rectangle in the `clientRecls` array.

Next comes the assignment of location and dimension values to the `hiliter` object's `style` property. The top and bottom are always pegged to whatever line is selected, so the `clientRecls` array is polled for the chosen entry's top and bottom properties. The previously calculated left value is assigned to the `hiliter` object's `pixelLeft` property, while the width is calculated by subtracting the left from the right coordinates. Notice that the top and left coordinates also take into account any vertical or horizontal scrolling of the entire body of the document. If you resize the window to a smaller size, line wrapping throws off the original line count. However, an invocation of `hilite()` from the `onResize` event handler applies the currently chosen line number to whatever content falls in that line after resizing.

### Listing 15-27: Using `getBoundingClientRect()`

```
<HTML>
<HEAD>
<TITLE>getClientRecls() and getBoundClientRect() Methods</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function hilite() {
 var hTop, hLeft, hRight, hBottom, hWidth
 var select = document.forms[0].choice
 var n = parseInt(select.options[select.selectedIndex].value) - 1
 var clientRecls = document.all.main.getClientRecls()
 var mainElem = document.all.main
 if (n >= 0 && n < clientRecls.length) {
 if (document.forms[0].fullWidth.checked) {
 hLeft = mainElem.getBoundingClientRect().left
 hRight = mainElem.getBoundingClientRect().right
 } else {
 hLeft = clientRecls[n].left
 hRight = clientRecls[n].right
 }
 }
 document.all.hiliter.style.pixelTop = clientRecls[n].top +
 document.body.scrollTop
 document.all.hiliter.style.pixelBottom = clientRecls[n].bottom
 document.all.hiliter.style.pixelLeft = hLeft + document.body.scrollLeft
}
```

```

 document.all.hiliter.style.pixelWidth = hRight - hLeft
 document.all.hiliter.style.visibility = "visible"
 } else if (n > 0) {
 alert("The content does not have that many lines.")
 document.all.hiliter.style.visibility = "hidden"
 }
}
</SCRIPT>
</HEAD>
<BODY onResize="hilite()">
<H1>getClientRects() and getBoundClientRect() Methods</H1>
<HR>
<FORM>
Choose a line to highlight:
<SELECT NAME="choice" onChange="hilite()">
<OPTION VALUE=0>
<OPTION VALUE=1>1
<OPTION VALUE=2>2
<OPTION VALUE=3>3
<OPTION VALUE=4>4
<OPTION VALUE=5>5
<OPTION VALUE=6>6
<OPTION VALUE=7>7
<OPTION VALUE=8>8
<OPTION VALUE=9>9
<OPTION VALUE=10>10
<OPTION VALUE=11>11
<OPTION VALUE=12>12
<OPTION VALUE=13>13
<OPTION VALUE=14>14
<OPTION VALUE=15>15
</SELECT>

<INPUT NAME="fullWidth" TYPE="checkbox" onClick="hilite()">
Full Width (bounding rectangle)
</FORM>

<P>Lorem ipsum dolor sit amet, consectetur adipiscing elit, sed do

```

*Continued*

**Listing 15-27 (continued)**

```

<DIV ID="hiliter"
STYLE="position:absolute; background-color:yellow; z-index:-1;
visibility:hidden">
</DIV>
</BODY>
</HTML>

```

Because the `z-index` style property of the `hiliter` element is set to `-1`, the element always appears beneath the primary content on the page. If the user selects a line number beyond the current number of lines in the main element, the `hiliter` element is hidden.

**getClientRects()**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

**Example**

See Listing 15-27, which demonstrates the differences between `getClientRects()` and `getBoundingClientRect()` and shows how you can use the two together.

**getElementsByTagName("tagName")**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

**Example**

Use The Evaluator (Chapter 13) to experiment with the `getElementsByTagName()` method. Enter the following statements one at a time into the upper text box and study the results:

```
document.body.getElementsByTagName("DIV")
```

```
document.body.getElementsByTagName("DIV").length
document.getElementById("myTable").getElementsByTagName("TD").length
```

Because the `getElementsByTagName()` method returns an array of objects, you can use one of those returned values as a valid element reference:

```
document.getElementsByTagName("FORM")[0].getElementsByTagName("INPUT").length
```

## `getExpression("attributeName")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

See Listing 15-32 for the `setExpression()` method. This listing demonstrates the kinds of values returned by `getExpression()`.

## `hasChildNodes()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `hasChildNodes()` method. If you enter the following statement into the topmost text box:

```
document.getElementById("myP").hasChildNodes()
```

the returned value is `true`. You can find out how many nodes there are by getting the `length` of the `childNodes` array:

```
document.getElementById("myP").childNodes.length
```

This expression reveals a total of three nodes: the two text nodes and the EM element between them. Check out whether the first text node has any children:

```
document.getElementById("myP").childNodes[0].hasChildNodes()
```

The response is `false` because text fragments do not have any nested nodes. But check out the EM element, which is the second child node of the `myP` element:

```
document.getElementById("myP").childNodes[1].hasChildNodes()
```

The answer is `true` because the EM element has a text fragment node nested within it. Sure enough, the statement

```
document.getElementById("myP").childNodes[1].childNodes.length
```

yields a node count of 1. You can also go directly to the EM element in your references:

```
document.getElementById("myEM").hasChildNodes()
document.getElementById("myEM").childNodes.length
```

If you want to see the properties of the text fragment node inside the EM element, enter the following into the lower text box:

```
document.getElementById("myEM").childNodes[0]
```

You can see that the `data` and `nodeValue` properties for the text fragment return the text "all".

`insertAdjacentElement("location",  
elementObject)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `insertAdjacentElement()` method. The goal of the experiment is to insert a new H1 element above the `myP` element.

All actions require you to enter a sequence of statements in the topmost text box. Begin by storing a new element in the global variable `a`:

```
a = document.createElement("H1")
```

Give the new object some text:

```
a.innerHTML = "New Header"
```

Now, insert this element before the start of the `myP` object:

```
myP.insertAdjacentElement("beforeBegin", a)
```

Notice that you have not assigned an `id` property value to the new element. But because the element was inserted by reference, you can modify the inserted object by changing the object stored in the `a` variable:

```
a.style.color = "red"
```

The inserted element is also part of the document hierarchy, so you can access it through hierarchy references such as `myP.previousSibling`.

The parent element of the newly inserted element is the `BODY`. Thus, you can inspect the current state of the HTML for the rendered page by entering the following statement into the topmost text box:

```
document.body.innerHTML
```

If you scroll down past the first form, you can find the `<H1>` element that you added along with the `STYLE` attribute.

```
insertAdjacentHTML("location", "HTMLtext")
insertAdjacentText("location", "text")
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with these two methods. The example here demonstrates the result of employing both methods in an attempt to add some HTML to the beginning of the `myP` element.

Begin by assigning a string of HTML code to the global variable `a`:

```
a = "<B ID='myB'>Important News!"
```

Because this HTML is to go on the same line as the start of the `myP` paragraph, use the `afterBegin` parameter for the insert method:

```
myP.insertAdjacentHTML("afterBegin", a)
```

Notice that there is no space after the exclamation mark of the inserted HTML. But to prove that the inserted HTML is genuinely part of the document's object model, you can now insert the text of a space after the B element whose ID is myB:

```
myB.insertAdjacentText("afterEnd", " ")
```

Each time you evaluate the preceding statement (by repeatedly clicking the Evaluate button or pressing Enter with the cursor in the topmost field), an additional space is added.

You should also see what happens when the string to be inserted with `insertAdjacentText()` contains HTML tags. Reload The Evaluator and enter the following two statements into the topmost field, evaluating each one in turn:

```
a = "<B ID='myB'>Important News!"
myP.insertAdjacentText("afterBegin", a)
```

The HTML is not interpreted but is displayed as plain text. There is no object named myB after executing this latest insert method.

```
insertBefore(newChildNodeObject[,
referenceChildNode])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Listing 15-28 demonstrates how the `insertBefore()` method can insert child elements (LI) inside a parent (OL) at different locations, depending on the second parameter. A text box enables you to enter your choice of text and/or HTML for insertion at various locations within the OL element. If you don't specify a position, the second parameter of `insertBefore()` is passed as `null` — meaning that the new child node is added to the end of the existing children. But choose a spot from the select list where you want to insert the new item. The value of each SELECT list option is an index of one of the first three child nodes of the OL element.

### Listing 15-28: Using the `insertBefore()` Method

```
<HTML>
<HEAD>
```

```

<TITLE>insertBefore() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function doInsert(form) {
 if (form.newText) {
 var newChild = document.createElement("LI")
 newChild.innerHTML = form.newText.value
 var choice = form.itemIndex.options[form.itemIndex.selectedIndex].value
 var insertPoint = (isNaN(choice)) ?
 null : document.getElementById("myUL").childNodes[choice]
 document.getElementById("myUL").insertBefore(newChild, insertPoint)
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>insertBefore() Method</H1>
<HR>
<FORM onSubmit="return false">
<P>Enter text or HTML for a new list item:
<INPUT TYPE="text" NAME="newText" SIZE=40 VALUE=""></P>
<P>Before which existing item?
<SELECT NAME="itemIndex">
 <OPTION VALUE=null>None specified
 <OPTION VALUE=0>1
 <OPTION VALUE=1>2
 <OPTION VALUE=2>3
</SELECT></P>
<INPUT TYPE="button" VALUE="Insert Item" onClick="doInsert(this.form)">
</FORM>

<OL ID="myUL">
 Originally the First Item
 Originally the Second Item
 Originally the Third Item

</BODY>
</HTML>

```

`item(index | "index" [, subIndex])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `item()` method. Type the following statements into the topmost text box and view the results for each:

NN6 and IE5

```
document.getElementById("myP").childNodes.length
document.getElementById("myP").childNodes.item(0).data
document.getElementById("myP").childNodes.item(1).nodeName
```

NN6, IE4, and IE5

```
document.forms[1].elements.item(0).type
```

IE4 and IE5

```
document.all.item("myP").outerHTML
myP.outerHTML
```

In the last two examples, both statements return the same string. The first example is helpful when your script is working with a string version of an object's name. If your script already knows the object reference, then the second approach is more efficient and compact.

## `mergeAttributes("sourceObject")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

## Example

Listing 15-29 demonstrates the usage of `mergeAttributes()` in the process of replicating the same form input field while assigning a unique ID to each new field. So you can see the results as you go, I display the HTML for each input field in the field.

The `doMerge()` function begins by generating two new elements: a `P` and an `INPUT` element. Because these newly created elements have no properties associated with them, a unique ID is assigned to the `INPUT` element via the `uniqueID` property. Attributes from the field in the source code (`field1`) are merged into the new `INPUT` element. Thus, all attributes except `name` and `id` are copied to the new element. The `INPUT` element is inserted into the `P` element, and the `P` element is appended to the document's form element. Finally, the `outerHTML` of the new element is displayed in its field. Notice that except for the `NAME` and `ID` attributes, all

others are copied. This includes style sheet attributes and event handlers. To prove that the event handler works in the new elements, you can add a space to any one of them and press Tab to trigger the `onChange` event handler that changes the content to all uppercase characters.

### Listing 15-29: Using the `mergeAttributes()` Method

```
<HTML>
<HEAD>
<TITLE>mergeAttributes() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function doMerge(form) {
 var newPElem = document.createElement("P")
 var newInputElem = document.createElement("INPUT")
 newInputElem.id = newInputElem.uniqueID
 newInputElem.mergeAttributes(form.field1)
 newPElem.appendChild(newInputElem)
 form.appendChild(newPElem)
 newInputElem.value = newInputElem.outerHTML
}
// called by onChange event handler of fields
function upperMe(field) {
 field.value = field.value.toUpperCase()
}
</SCRIPT>
</HEAD>
<BODY onLoad="document.expandable.field1.value =
document.expandable.field1.outerHTML">
<H1>mergeAttributes() Method</H1>
<HR>
<FORM NAME="expandable" onSubmit="return false">
<P><INPUT TYPE="button" VALUE="Append Field 'Clone'"
onClick="doMerge(this.form)"></P>
<P><INPUT TYPE="text" NAME="field1" ID="FIELD1" SIZE=120 VALUE="" STYLE="font-
size:9pt" onChange="upperMe(this)"></P>
</FORM>
</BODY>
</HTML>
```

## normalize()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

## Example

Use The Evaluator to experiment with the `normalize()` method in NN6. The following sequence adds a text node adjacent to one in the `myP` element. A subsequent invocation of the `normalize()` method removes the division between the adjacent text nodes.

Begin by confirming the number of child nodes of the `myP` element:

```
document.getElementById("myP").childNodes.length
```

Three nodes initially inhabit the element. Next, create a text node and append it as the last child of the `myP` element:

```
a = document.createTextNode("This means you!")
document.getElementById("myP").appendChild(a)
```

With the new text now rendered on the page, the number of child nodes increases to four:

```
document.getElementById("myP").childNodes.length
```

You can see that the last child node of `myP` is the text node you just created:

```
document.getElementById("myP").lastChild.nodeValue
```

But by invoking `normalize()` on `myP`, all adjacent text nodes are accumulated into single nodes:

```
document.getElementById("myP").normalize()
```

You can now see that the `myP` element is back to three child nodes, and the last child is a combination of the two previously distinct, but adjacent, text nodes:

```
document.getElementById("myP").childNodes.length
document.getElementById("myP").lastChild.nodeValue
```

`releaseCapture()`  
`setCapture(containerBoolean)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

## Example

Listing 15-30 demonstrates the usage of `setCapture()` and `releaseCapture()` in a “quick-and-dirty” context menu for IE5+/Windows. The job of the context menu is to present a list of numbering styles for the ordered list of items on the page. Whenever the user brings up the context menu atop the OL element, the custom context menu appears. Event capture is turned on in the process to prevent mouse actions elsewhere on the page from interrupting the context menu choice. Even a click on the link set up as the title of the list is inhibited while the context menu is visible. A click anywhere outside of the context menu hides the menu. Clicking a choice in the menu changes the `listStyleType` property of the OL object and hides the menu. Whenever the context menu is hidden, event capture is turned off so that clicking on the page (such as the link) works as normal.

For this design, `onClick`, `onMouseOver`, and `onMouseOut` event handlers are assigned to the DIV element that contains the context menu. To trigger the display of the context menu, the OL element has an `onContextMenu` event handler. This handler invokes the `showContextMenu()` function. In this function, event capture is assigned to the context menu DIV object. The DIV is also positioned at the location of the click before it is set to be visible. To prevent the system’s regular context menu from also appearing, the event object’s `returnValue` property is set to `false`.

Now that all mouse events on the page go through the `contextMenu` DIV object, let’s examine what happens with different kinds of events triggered by user action. As the user rolls the mouse, a flood of `mouseover` and `mouseout` events fire. The event handlers assigned to the DIV manage these events. But notice that the two event handlers, `highlight()` and `unhighlight()`, perform action only when the `srcElement` property of the event is one of the menu items in the DIV. Because the page has no other `onMouseOver` or `onMouseOut` event handlers defined for elements up the containment hierarchy, you do not have to cancel event bubbling for these events.

When a user clicks the mouse button, different things happen depending on whether event capture is enabled. Without event capture, the `click` event bubbles up from wherever it occurred to the `onClick` event handler in the BODY element. (An alert dialog box displays to let you know when the event reaches the BODY.) But with event capture turned on (the context menu is showing), the `handleClick()` event handler takes over to apply the desired choice whenever the click is atop one of the context menu items. For all `click` events handled by this function, the context menu is hidden and the `click` event is canceled from bubbling up any higher (no alert dialog box appears). This takes place whether the user makes a choice in the context menu or clicks anywhere else on the page. In the latter case, all you need is for the context menu to go away like the real context menu does. For added insurance, the `onLoseCapture` event handler hides the context menu when a user performs any of the actions just listed that cancel capture.

Listing 15-30: Using `setCapture()` and `releaseCapture()`

```

<HTML>
<STYLE TYPE="text/css">
#contextMenu {position:absolute; background-color:#cfcfcf;
border-style:solid; border-width:1px;
border-color:#EFEFEF #505050 #505050 #EFEFEF;
padding:3px 10px; font-size:8pt; font-family:Arial, Helvetica;
line-height:150%; visibility:hidden}
.menuItem {color:black}
.menuItemOn {color:white}
OL {list-style-position:inside; font-weight:bold; cursor:nw-resize}
LI {font-weight:normal}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function showContextMenu() {
contextMenu.setCapture()
contextMenu.style.pixelTop = event.clientY + document.body.scrollTop
contextMenu.style.pixelLeft = event.clientX + document.body.scrollLeft
contextMenu.style.visibility = "visible"
event.returnValue = false
}

function revert() {
document.releaseCapture()
hideMenu()
}

function hideMenu() {
contextMenu.style.visibility = "hidden"
}

function handleClick() {
var elem = window.event.srcElement
if (elem.id.indexOf("menuItem") == 0) {
shapesList.style.listStyleType = elem.LISTTYPE
}
revert()
event.cancelBubble = true
}

function highlight() {
var elem = event.srcElement
if (elem.className == "menuItem") {
elem.className = "menuItemOn"
}
}
}

```

```

function unhighlight() {
 var elem = event.srcElement
 if (elem.className == "menuItem0n") {
 elem.className = "menuItem"
 }
}
</SCRIPT>
<BODY onClick="alert('You reached the document object.')" >
<OL ID="shapesList" onContextMenu="showContextMenu()">
Three-Dimensional Shapes
Circular Cylinder
Cube
Rectangular Prism
Regular Right Pyramid
Right Circular Cone
Sphere

<DIV ID="contextMenu" onLoseCapture="hideMenu()" onClick="handleClick()"
onMouseOver="highlight()" onMouseOut="unhighlight()">
<SPAN ID="menuItem1" CLASS="menuItem" LISTTYPE="upper-
alpha">A,B,C,...

<SPAN ID="menuItem2" CLASS="menuItem" LISTTYPE="lower-
alpha">a,b,c,...

<SPAN ID="menuItem3" CLASS="menuItem" LISTTYPE="upper-
roman">I,II,III,...

<SPAN ID="menuItem4" CLASS="menuItem" LISTTYPE="lower-
roman">i,ii,iii,...

1,2,3,...

</DIV>
</BODY>
</HTML>

```

`removeAttribute("attributeName" [, caseSensitivity])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `removeAttribute()` method for the elements in the page. See the examples for the `setAttribute()`

method later in this chapter, and enter the corresponding `removeAttribute()` statements in the top text box. Interlace statements using `getAttribute()` to verify the presence or absence of each attribute.

```
removeAttributeNode(attributeNode)
setAttributeNode(attributeNode)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `setAttributeNode()` and `removeAttributeNode()` methods for the P element in the page. The task is to create and add a `STYLE` attribute to the P element. Begin by creating a new attribute and storing it temporarily in the global variable `a`:

```
a = document.createAttribute("style")
```

Assign a value to the attribute object:

```
a.nodeValue = "color:red"
```

Now insert the new attribute into the P element:

```
document.getElementById("myP").setAttributeNode(a)
```

The paragraph changes color in response to the newly added attribute.

Due to the NN6 bug that won't allow the method to return a reference to the newly inserted attribute node, you can artificially obtain such a reference:

```
b = document.getElementById("myP").getAttributeNode("style")
```

Finally, use the reference to the newly added attribute to remove it from the element:

```
document.getElementById("myP").removeAttribute(b)
```

Upon removing the attribute, the paragraph resumes its initial color. See the example for the `setAttribute()` method later in this chapter to discover how you can perform this same kind of operation with `setAttribute()`.

## removeBehavior(*ID*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

See Listings 15-19a and 15-19b earlier in this chapter for examples of how to use `addBehavior()` and `removeBehavior()`.

## removeChild(*nodeObject*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

You can see an example of `removeChild()` as part of Listing 15-21 earlier in this chapter.

## removeEventListener()

See `addEventListener()`.

## removeExpression("*propertyName*")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

You can experiment with all three expression methods in The Evaluator (Chapter 13). The following sequence adds an expression to a style sheet property of the `myP` element on the page and then removes it.

To begin, enter the number 24 in the bottom one-line text box in The Evaluator (but don't press Enter or click the List Properties button). This is the value used in the expression to govern the `fontSize` property of the `myP` object. Next, assign an expression to the `myP` object's `style` object by entering the following statement into the topmost text box:

```
myP.style.setExpression("fontSize","document.forms[0].inspector.value","JScript")
```

You can now enter different font sizes into the lower text box and have the values immediately applied to the `fontSize` property. (Keyboard events in the text box automatically trigger the recalculation.) The default unit is `px`, but you can also append other units (such as `pt`) to the value in the text field to see how different measurement units influence the same numeric value.

Before proceeding to the next step, enter a value other than 16 (the default `fontSize` value). Finally, enter the following statement in the topmost text box to disconnect the expression from the property:

```
myP.style.removeExpression("fontSize")
```

Notice that although you can no longer adjust the font size from the lower text box, the most recent value assigned to it still sticks to the element. To prove it, enter the following statement in the topmost text box to see the current value:

```
myP.style.fontSize
```

## removeNode(*removeChildrenFlag*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Examine Listing 15-21 for the `appendChild()` method to understand the difference between `removeChild()` and `removeNode()`. In the `restore()` function, you can replace this statement

```
mainObj.removeChild(oneChild)
```

in IE5+ with

```
oneChild.removeNode(true)
```

The difference is subtle, but it is important to understand. See Listing 15-31 later in this chapter for another example of the `removeNode()` method.

```
replaceAdjacentText("location", "text")
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `replaceAdjacentText()` method. Enter each of the following statements into the top text box and watch the results in the `myP` element (and its nested `myEM` element) below the solid rule:

```
document.all.myEM.replaceAdjacentText("afterBegin", "twenty")
```

Notice that the `myEM` element's new text picks up the behavior of the element. In the meantime, the replaced text (`all`) is returned by the method and displayed in the Results box.

```
document.all.myEM.replaceAdjacentText("beforeBegin", "We need ")
```

All characters of the text fragment, including spaces, are replaced. Therefore, you may need to supply a trailing space, as shown here, if the fragment you replace has a space.

```
document.all.myP.replaceAdjacentText("beforeEnd", " good people.")
```

This is another way to replace the text fragment following the `myEM` element, but it is also relative to the surrounding `myP` element. If you now attempt to replace text after the end of the `myP` block-level element,

```
document.all.myP.replaceAdjacentText("afterEnd", "Hooray!")
```

the text fragment is inserted after the end of the `myP` element's tag set. The fragment is just kind of floating in the document object model as an unlabeled text node.

## `replaceChild(newNodeObject, oldNodeObject)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

You can see an example of `replaceChild()` as part of Listing 15-21 earlier in this chapter.

## `replaceNode("newNodeObject")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-31 demonstrates three node-related methods: `removeNode()`, `replaceNode()`, and `swapNode()`. These methods work in IE5+ only.

The page rendered from Listing 15-31 begins with a UL type list of four items. Four buttons control various aspects of the node structure of this list element. The first button invokes the `replace()` function, which changes the UL type to OL. To do this, the function must temporarily tuck away all child nodes of the original UL element so that they can be added back into the new OL element. At the same time, the old UL node is stored in a global variable (`oldNode`) for restoration in another function.

To replace the UL node with an OL, the `replace()` function creates a new, empty OL element and assigns the `myOL` ID to it. Next, the children (LI elements) are stored en masse as an array in the variable `innards`. The child nodes are then inserted into the empty OL element, using the `insertBefore()` method. Notice that as each child element from the `innards` array is inserted into the OL element, the child element is removed from the `innards` array. That's why the loop to insert the child nodes is a `while` loop that constantly inserts the first item of the `innards` array to the new element. Finally, the `replaceNode()` method puts the new node in the old node's place, while the old node (just the UL element) is stored in `oldNode`.

The `restore()` function operates in the inverse direction of the `replace()` function. The same juggling of nested child nodes is required.

The third button invokes the `swap()` function, whose script exchanges the first and last nodes. The `swapNode()` method, like the others in this discussion, operates from the point of view of the node. Therefore, the method is attached to one of the swapped nodes, while the other node is specified as a parameter. Because of the nature of the OL element, the number sequence remains fixed but the text of the LI node swaps.

To demonstrate the `removeNode()` method, the fourth function removes the last child node of the list. Each call to `removeNode()` passes the `true` parameter to guarantee that the text nodes nested inside each LI node are also removed. Experiment with this method by setting the parameter to `false` (the default). Notice how the parent-child relationship changes when you remove the LI node.

### Listing 15-31: Using Node-Related Methods

```
<HTML>
<HEAD>
<TITLE>removeNode(), replaceNode(), and swapNode() Methods</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// store original node between changes
var oldNode

// replace UL node with OL
function replace() {
 if (document.all.myUL) {
 var newNode = document.createElement("OL")
 newNode.id = "myOL"
 var innards = document.all.myUL.children
 while (innards.length > 0) {
 newNode.insertBefore(innards[0])
 }
 oldNode = document.all.myUL.replaceNode(newNode)
 }
}

// restore OL to UL
function restore() {
 if (document.all.myOL && oldNode) {
 var innards = document.all.myOL.children
 while (innards.length > 0) {
 oldNode.insertBefore(innards[0])
 }
 document.all.myOL.replaceNode(oldNode)
 }
}
}
```

*Continued*

`scrollIntoView(topAlignFlag)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

Use The Evaluator (Chapter 13) to experiment with the `scrollIntoView()` method. Resize the browser window height so that you can see only the topmost text box and the Results textarea. Enter each of the following statements into the top text box and see where the `myP` element comes into view:

```
myP.scrollIntoView()
myP.scrollIntoView(false)
```

Expand the height of the browser window until you can see part of the table lower on the page. If you enter

```
myTable.scrollIntoView(false)
```

into the top text box, the page scrolls to bring the bottom of the table to the bottom of the window. But if you use the default parameter (`true` or empty),

```
myTable.scrollIntoView()
```

the page scrolls as far as it can in an effort to align the top of the element as closely as possible to the top of the window. The page cannot scroll beyond its normal scrolling maximum (although if the element is a positioned element, you can use dynamic positioning to place it wherever you want—including “off the page”). Also, if you shrink the window and try to scroll the top of the table to the top of the window, be aware that the TABLE element contains a CAPTION element so the caption is flush with the top of the window.

`setActive()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

Use The Evaluator (Chapter 13) to compare the `setActive()` and `focus()` methods. With the page scrolled to the top and the window sized so that you cannot see the sample check box near the bottom of the page, enter the following statement into the top text box:

```
document.forms[1].myCheckbox.setActive()
```

Scroll down to see that the checkbox has operational focus (press the spacebar to see). Now, scroll back to the top and enter the following:

```
document.forms[1].myCheckbox.focus()
```

This time, the checkbox gets focus and the page automatically scrolls the object into view.

```
setAttribute("attributeName", value[,
caseSensitivity])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `setAttribute()` method for the elements in the page. For IE4, use the `document.all` notation; IE5 and NN6 understand the W3C standard `getElementById()` method of addressing an element.

Setting attributes can have immediate impact on the layout of the page (just as setting an object's properties can). Enter these sample statements into the top text box to view attribute values:

IE4+:

```
document.all.myTable.setAttribute("width", "80%")
document.all.myTable.setAttribute("border", "5")
```

IE5+/NN6:

```
document.getElementById("myTable").setAttribute("width", "80%")
document.getElementById("myTable").setAttribute("border", "5")
```

## setAttributeNode()

See `removeAttributeNode()`.

## setCapture(*containerBoolean*)

See `releaseCapture()`.

## setExpression("propertyName", "expression", "language")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-32 shows the `setExpression()`, `recalc()`, and `getExpression()` methods at work in a DHTML-based clock. Figure 15-1 shows the clock. As time clicks by, the bars for hours, minutes, and seconds adjust their widths to reflect the current time. At the same time, the `innerHTML` of SPAN elements to the right of each bar display the current numeric value for the bar.

The dynamically calculated values in this example are based on the creation of a new date object over and over again to get the current time from the client computer clock. It is from the date object (stored in the variable called `now`) that the hour, minute, and second values are retrieved. Some other calculations are involved so that a value for one of these time components is converted into a pixel value for the width of the bars. The bars are divided into 24 (for the hours) and 60 (for the minutes and seconds) parts, so the scale for the two types differs. For the 60-increment bars in this application, each increment is set to 5 pixels (stored in `shortWidth`); the 24-increment bars are 2.5 times the `shortWidth`.

As the document loads, the three SPAN elements for the colored bars are given no width, which means that they assume the default width of zero. But after the page loads, the `onLoad` event handler invokes the `init()` function, which sets the initial values for each bar's width and the text (`innerHTML`) of the three labeled spans. Once these initial values are set, the `init()` function invokes the `updateClock()` function.

In the `updateClock()` function, a new date object is created for the current instant. The `document.recalc()` method is called, instructing the browser to recalculate the expressions that were set in the `init()` function and assign the new values to the properties. To keep the clock “ticking,” the `setTimeout()` method is set to invoke this same `updateClock()` function in one second.

To see what the `getExpression()` method does, you can click the button on the page. It simply displays the returned value for one of the attributes that you assign using `setExpression()`.

### Listing 15-32: Dynamic Properties

```
<HTML>
<HEAD>
<TITLE>getExpression(), setExpression(), and recalc() Methods</TITLE>
<STYLE TYPE="text/css">
TH {text-align:right}

</FORM>
</BODY>
</HTML>

```

Figure 15-1: A clock controlled by dynamic properties

### swapNode(*otherNodeObject*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

### Example

See Listing 15-31 (the replaceNode() method) for an example of the swapNode() method in action.

### tags("tagName")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `tags()` method. Enter the following statements one at a time into the upper text box and study the results:

```
document.all.tags("DIV")
document.all.tags("DIV").length
myTable.all.tags("TD").length
```

Because the `tags()` method returns an array of objects, you can use one of those returned values as a valid element reference:

```
document.all.tags("FORM")[1].elements.tags("INPUT").length
```

```
urns("behaviorURN")
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

## Example

In case the `urns()` method is reconnected in the future, you can add a button and function to Listing 15-19b that reveals whether the `makeHot.htc` behavior is attached to the `myP` element. Such a function looks like this:

```
function behaviorAttached() {
 if (document.all.urns("makeHot")) {
 alert("There is at least one element set to \'makeHot\'.")
 }
}
```

## Event handlers

```
onActivate
onBeforeDeactivate
onDeactivate
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

You can modify Listing 15-34 later in this chapter by substituting `onActivate` for `onFocus` and `onDeactivate` for `onBlur`.

Use The Evaluator (Chapter 13) to experiment with the `onBeforeDeactivate` event handler. To begin, set the `myP` element so it can accept focus:

```
myP.tabIndex = 1
```

If you repeatedly press the Tab key, the `myP` paragraph will eventually receive focus — indicated by the dotted rectangle around it. To see how you can prevent the element from losing focus, assign an anonymous function to the `onBeforeDeactivate` event handler, as shown in the following statement:

```
myP.onbeforedeactivate = new Function("event.returnValue=false")
```

Now you can press Tab all you like or click other focusable elements all you like, and the `myP` element will not lose focus until you reload the page (which clears away the event handler). Please do not do this on your pages unless you want to infuriate and alienate your site visitors.

## onBeforeCopy

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

### Example

You can use the `onBeforeCopy` event handler to preprocess information prior to an actual copy action. In Listing 15-33, the function invoked by the second paragraph element's `onBeforeCopy` event handler selects the entire paragraph so that the user can select any character(s) in the paragraph to copy the entire paragraph into the clipboard. You can paste the results into the textarea to verify the operation. By assigning the paragraph selection to the `onBeforeCopy` event handler, the page notifies the user about what the copy operation will entail prior to making the menu choice. Had the operation been deferred to the `onCopy` event handler, the selection would have been made after the user chose Copy from the menu.

**Listing 15-33: The onBeforeCopy Event Handler**

```

<HTML>
<HEAD>
<TITLE>onBeforeCopy Event Handler</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function selectWhole() {
 var obj = window.event.srcElement
 var range = document.body.createTextRange()
 range.moveToElementText(obj)
 range.select()
 event.returnValue = false
}
</SCRIPT>
</HEAD>
<BODY>
<H1>onBeforeCopy Event Handler</H1>
<HR>
<P>Select one or more characters in the following paragraph. Then
execute a Copy command via Edit or context menu.</P>
<P ID="myP" onBeforeCopy="selectWhole()">Lorem ipsum dolor sit amet,
consectetur adipiscing elit, sed do eiusmod tempor incididunt ut
labore et dolore magna aliqua. Ut enim adminim veniam, quis nostrud
exercitation ullamco laboris nisi ut aliquip ex ea commodo consequat.</P>
<FORM>
<P>Paste results here:

<TEXTAREA NAME="output" COLS="60" ROWS="5"></TEXTAREA>
</P>
</FORM>
</BODY>
</HTML>

```

## onBeforeCut

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

You can use the `onBeforeCut` event handler to preprocess information prior to an actual cut action. You can try this by editing a copy of Listing 15-33, changing the

`onBeforeCopy` event handler to `onBeforeCut`. Notice that in its original form, the example does not activate the Cut item in either the context or Edit menu when you select some text in the second paragraph. But by assigning a function to the `onBeforeCut` event handler, the menu item is active, and the entire paragraph is selected from the function that is invoked.

## onBeforeDeactivate

See `onActivate`.

## onBeforeEditFocus

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator to explore the `onBeforeEditFocus` in IE5.5+. In the following sequence, you assign an anonymous function to the `onBeforeEditFocus` event handler of the `myP` element. The function turns the text color of the element to red when the event handler fires:

```
myP.onbeforeeditfocus = new Function("myP.style.color='red'")
```

Now turn on content editing for the `myP` element:

```
myP.contentEditable = true
```

If you now click inside the `myP` element on the page to edit its content, the text turns to red before you begin editing. In a page scripted for this kind of user interface, you would include some control that turns off editing and changes the color to normal.

If you wish to learn more about HTML content editing via the DHTML Editing ActiveX control, visit <http://msdn.microsoft.com/workshop/browser/mshhtml/>.

## onBeforePaste

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

### Example

See Listing 15-45 for the `onPaste` event handler (later in this chapter) to see how the `onBeforePaste` and `onPaste` event handlers work together.

## onBlur

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

More often than not, a page author uses the `onBlur` event handler to exert extreme control over the user, such as preventing a user from exiting out of a text box unless that user types something into the box. This is not a Web-friendly practice, and it is one that I discourage because there are intelligent ways to ensure a field has something typed into it before a form is submitted (see Chapter 43). Listing 15-34 simply demonstrates the impact of the `TABINDEX` attribute in an IE5/Windows element with respect to the `onBlur` and `onFocus` events. Notice that as you press the Tab key, only the second paragraph issues the events even though all three paragraphs have event handlers assigned to them.

### Listing 15-34: `onBlur` and `onFocus` Event Handlers

```
<HTML>
<HEAD>
<TITLE>onBlur and onFocus Event Handlers</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function showBlur() {
 var id = event.srcElement.id
 alert("Element \" + id + "\" has blurred.")
}
```

*Continued*

## Listing 15-34 (continued)

```

}
function showFocus() {
 var id = event.srcElement.id
 alert("Element \"" + id + "\" has received focus.")
}
</SCRIPT>
</HEAD>
<BODY>
<H1 ID="H1" TABINDEX=2>onBlur and onBlur Event Handlers</H1>
<HR>
<P ID="P1" onBlur="showBlur()" onFocus="showFocus()">Lorem ipsum
dolor sit amet, consectetur adipiscing elit, sed do eiusmod tempor
incididunt ut labore et dolore magna aliqua. Ut enim adminim veniam,

peish ba useing phen roxas. Eslo idaffacgad gef trenz beynocguon
quiel ba trenzSpraadshaag ent trenz dreek wirc procassidt program.</P>

</BODY>
</HTML>

```

## onClick

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The `onClick` event handler is one of the simplest to grasp and use. Listing 15-35 demonstrates its interaction with the `ondblclick` event handler and shows you how to prevent a link's intrinsic action from activating when combined with `click` events. As you click and/or double-click the link, the status bar displays a message

associated with each event. Notice that if you double-click, the `click` event fires first with the first message immediately replaced by the second. For demonstration purposes, I show both backward-compatible ways of cancelling the link's intrinsic action. In practice, decide on one style and stick with it.

### Listing 15-35: Using `onClick` and `onDb1Click` Event Handlers

```
<HTML>
<HEAD>
<TITLE>onClick and onDb1Click Event Handlers</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var msg = ""
function showClick() {
 msg = "The element has been clicked. "
 status = msg
}
function showDb1Click() {
 msg = "The element has been double-clicked."
 status = msg
 return false
}
</SCRIPT>
</HEAD>
<BODY>
<H1>onClick and onDb1Click Event Handlers</H1>
<HR>
<A HREF="#" onClick="showClick();return false"
onDb1Click="return showDb1Click()">
A sample link.
</BODY>
</HTML>
```

## onContextMenu

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

See Listing 15-30 earlier in this chapter for an example of using the `onContextMenu` event handler with a custom context menu.

## onCopy onCut

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-36 shows both the `onBeforeCut` and `onCut` event handlers in action (as well as `onBeforePaste` and `onPaste`). Notice how the `handleCut()` function not only stuffs the selected word into the `clipboardData` object, but it also erases the selected text from the table cell element from where it came. If you replace the `onBeforeCut` and `onCut` event handlers with `onBeforeCopy` and `onCopy` (and change `handleCut()` to not eliminate the inner text of the event source element), the operation works with copy and paste instead of cut and paste. I demonstrate this later in the chapter in Listing 15-45.

### Listing 15-36: Cutting and Pasting under Script Control

```
<HTML>
<HEAD>
<TITLE>onBeforeCut and onCut Event Handlers</TITLE>
<STYLE TYPE="text/css">
TD {text-align:center}
TH {text-decoration:underline}
.blanks {text-decoration:underline}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function selectWhole() {
 var obj = window.event.srcElement
 var range = document.body.createTextRange()
 range.moveToElementText(obj)
 range.select()
 event.returnValue = false
}
function handleCut() {
 var rng = document.selection.createRange()
 clipboardData.setData("Text",rng.text)
 var elem = event.srcElement
 elem.innerHTML = ""
 event.returnValue = false
}
```

## onDb1Click

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

See Listing 15-35 (for the `onClick` event handler) to see the `onDb1Click` event in action.

## onDrag

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-37 shows several drag-related event handlers in action. The page resembles the example in Listing 15-36, but the scripting behind the page is quite different. In this example, the user is encouraged to select individual words from the Nouns and Adjectives columns and drag them to the blanks of the sentence. To beef up the demonstration, Listing 15-37 shows you how to pass the equivalent of array data from a drag source to a drag target. At the same time, the user has a fixed amount of time (two seconds) to complete each drag operation.

The `onDragStart` and `onDrag` event handlers are placed in the `<BODY>` tag because those events bubble up from any element that the user tries to drag. The scripts invoked by these event handlers filter the events so that the desired action is triggered only by the “hot” elements inside the table. This approach to event handlers prevents you from having to duplicate event handlers (or IE `<SCRIPT FOR=>` tags) for each table cell.

The `onDragStart` event handler invokes `setupDrag()`. This function cancels the `onDragStart` event except when the target element (in other words, the one about to be dragged) is one of the TD elements inside the table. To make this application smarter about what kind of word is dragged to which blank, it passes not only the word’s text, but also some extra information about the word. This lets another event handler verify that a noun has been dragged to the first blank, while an adjective has been dragged to the second blank. To help with this effort, class names are

assigned to the TD elements to distinguish the words from the Nouns column from the words of the Adjectives column. The `setupDrag()` function generates an array consisting of the `innerText` of the event's source element plus the element's class name. But the `event.dataTransfer` object cannot store array data types, so the `Array.join()` method converts the array to a string with a colon separating the entries. This string, then, is stuffed into the `event.dataTransfer` object. The object is instructed to render the cursor display during the drag-and-drop operation so that when the cursor is atop a drop target, the cursor is the "copy" style. Finally, the `setupDrag()` function is the first to execute in the drag operation, so a timer is set to the current clock time to time the drag operation.

The `onDrag` event handler (in the BODY) captures the `onDrag` events that are generated by whichever table cell element is the source element for the action. Each time the event fires (which is a lot during the action), the `timeIt()` function is invoked to compare the current time against the reference time (global timer) set when the drag starts. If the time exceeds two seconds (2,000 milliseconds), an alert dialog box notifies the user. To close the alert dialog box, the user must unclick the mouse button to end the drag operation.

To turn the blank SPAN elements into drop targets, their `onDragEnter`, `onDragOver`, and `onDrop` event handlers must set `event.returnValue` to `false`; also, the `event.dataTransfer.dropEffect` property should be set to the desired effect (copy in this case). These event handlers are placed in the P element that contains the two SPAN elements, again for simplicity. Notice, however, that the `cancelDefault()` functions do their work only if the target element is one of the SPAN elements whose ID begins with "blank."

As the user releases the mouse button, the `onDrop` event handler invokes the `handleDrop()` function. This function retrieves the string data from `event.dataTransfer` and restores it to an array data type (using the `String.split()` method). A little bit of testing makes sure that the word type ("noun" or "adjective") is associated with the desired blank. If so, the source element's text is set to the drop target's `innerText` property; otherwise, an error message is assembled to help the user know what went wrong.

### Listing 15-37: Using Drag-Related Event Handlers

```
<HTML>
<HEAD>
<TITLE>Dragging Event Handlers</TITLE>
<STYLE TYPE="text/css">
TD {text-align:center}
TH {text-decoration:underline}
.blanks {text-decoration:underline}
</STYLE>
```

*Continued*

## Listing 15-37 (continued)

```
<SCRIPT LANGUAGE="JavaScript">
var timer
function setupDrag() {
 if (event.srcElement.tagName != "TD") {
 // don't allow dragging for any other elements
 event.returnValue = false
 } else {
 // setup array of data to be passed to drop target
 var passedData = [event.srcElement.innerText,
event.srcElement.className]
 // store it as a string
 event.dataTransfer.setData("Text", passedData.join(":"))
 event.dataTransfer.effectAllowed = "copy"
 timer = new Date()
 }
}
function timeIt() {
 if (event.srcElement.tagName == "TD" && timer) {
 if ((new Date()) - timer > 2000) {
 alert("Sorry, time is up. Try again.")
 timer = 0
 }
 }
}
function handleDrop() {
 var elem = event.srcElement
 var passedData = event.dataTransfer.getData("Text")
 var errMsg = ""
 if (passedData) {
 // reconvert passed string to an array
 passedData = passedData.split(":")
 if (elem.id == "blank1") {
 if (passedData[1] == "noun") {
 event.dataTransfer.dropEffect = "copy"
 event.srcElement.innerText = passedData[0]
 } else {
 errMsg = "You can't put an adjective into the noun placeholder."
 }
 } else if (elem.id == "blank2") {
 if (passedData[1] == "adjective") {
 event.dataTransfer.dropEffect = "copy"
 event.srcElement.innerText = passedData[0]
 } else {
 errMsg = "You can't put a noun into the adjective placeholder."
 }
 }
 }
}
```

## onDragEnter onDragLeave

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-38 shows the `onDragEnter` and `onDragLeave` event handlers in use. The simple page displays (via the status bar) the time of entry to one element of the page. When the dragged cursor leaves the element, the `onDragLeave` event handler hides the status bar message. No drop target is defined for this page, so when you drag the item, the cursor remains as the “no drop” cursor.

### Listing 15-38: Using `onDragEnter` and `onDragLeave` Event Handlers

```
<HTML>
<HEAD>
<TITLE>onDragEnter and onDragLeave Event Handlers</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function showEnter() {
 status = "Entered at: " + new Date()
 event.returnValue = false
}
function clearMsg() {
 status = ""
 event.returnValue = false
}
</SCRIPT>
</HEAD>
<BODY>
<H1 onDragEnter="showEnter()" onDragLeave="clearMsg()">
onDragEnter and onDragLeave Event Handlers
</H1>
<HR>
<P>Select any character(s) from this paragraph,
and slowly drag it around the page. When the dragging action enters the
large header above, the status bar displays when the onDragEnter
event handler fires. When you leave the header, the message is cleared
```

```
via the onDragLeave event handler.</P>
</BODY>
</HTML>
```

## onDragOver

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

See Listing 15-37 of the `onDrag` event handler to see how the `onDragOver` event handler contributes to making an element a drop target.

## onDragStart

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 15-37 of the `onDrag` event handler to see how to apply the `onDragStart` event handler in a typical drag-and-drop scenario.

## onDrop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

See Listing 15-37 of the `onDrag` event handler to see how to apply the `onDrop` event handler in a typical drag-and-drop scenario.

## onFilterChange

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 15-39 demonstrates how the `onFilterChange` event handler can trigger a second transition effect after another one completes. The `onLoad` event handler triggers the first effect. Although the `onFilterChange` event handler works with most of the same objects in IE4 as IE5, the filter object transition properties are not reflected in a convenient form. The syntax shown in Listing 15-39 uses the new ActiveX filter control found in IE5.5 (described in Chapter 30).

### Listing 15-39: Using the `onFilterChange` Event Handler

```
<HTML>
<HEAD>
<TITLE>onFilterChange Event Handler</TITLE>
<SCRIPT LANGUAGE=JavaScript>
function init() {
 image1.filters[0].apply()
 image2.filters[0].apply()
 start()
}

function start() {
 image1.style.visibility = "hidden"
 image1.filters[0].play()
}

function finish() {
 // verify that first transition is done (optional)
 if (image1.filters[0].status == 0) {
 image2.style.visibility = "visible"
 image2.filters[0].play()
 }
}
</SCRIPT>
</HEAD>
<BODY onLoad="init()">
<H1>onFilterChange Event Handler</H1>
<HR>
<P>The completion of the first transition ("circle-in")
```

```

triggers the second ("circle-out").
<BUTTON onClick="location.reload()">Play It Again</BUTTON></P>
<DIV ID="image1" STYLE="visibility:visible;
 position:absolute; top:150px; left:150px;
 filter:progID:DXImageTransform.Microsoft.Iris(irisstyle='CIRCLE',
 motion='in')">
 onFilterChange="finish()"><IMG SRC="desk1.gif" HEIGHT=90
 WIDTH=120></DIV>
<DIV ID="image2" STYLE="visibility:hidden;
 position:absolute; top:150px; left:150px;
 filter:progID:DXImageTransform.Microsoft.Iris(irisstyle='CIRCLE',
 motion='out')">
 </DIV>
</BODY>
</HTML>

```

## onFocus

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See Listing 15-34 earlier in this chapter for an example of the `onFocus` and `onBlur` event handlers.

## onHelp

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 15-40 is a rudimentary example of a context-sensitive help system that displays help messages tailored to the kind of text input required by different text fields. When the user gives focus to either of the text fields, a small legend appears to remind the user that help is available by a press of the F1 help key. IE5/Mac provides only generic help.

## Listing 15-40: Creating Context-Sensitive Help

```

<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function showNameHelp() {
 alert("Enter your first and last names.")
 event.cancelBubble = true
 return false
}
function showYOBHelp() {
 alert("Enter the four-digit year of your birth. For example: 1972")
 event.cancelBubble = true
 return false
}
function showGenericHelp() {
 alert("All fields are required.")
 event.cancelBubble = true
 return false
}
function showLegend() {
 document.all.legend.style.visibility = "visible"
}
function hideLegend() {
 document.all.legend.style.visibility = "hidden"
}
function init() {
 var msg = ""
 if (navigator.userAgent.indexOf("Mac") != -1) {
 msg = "Press \'help\' key for help."
 } else if (navigator.userAgent.indexOf("Win") != -1) {
 msg = "Press F1 for help."
 }
 document.all.legend.style.visibility = "hidden"
 document.all.legend.innerHTML = msg
}
</SCRIPT>
</HEAD>

<BODY onLoad="init()" onHelp="return showGenericHelp()">
<H1>onHelp Event Handler</H1>
<HR>
<P ID="legend" STYLE="visibility:hidden; font-size:10px"> </P>
<FORM>

 onFocus="showLegend()" onBlur="hideLegend()"
 onHelp="return showNameHelp()">

Year of Birth: <INPUT TYPE="text" NAME="YOB" SIZE=30
 onFocus="showLegend()" onBlur="hideLegend()"

```

```

 onHelp="return showYOBHelp()">
</FORM>
</BODY>
</HTML>

```

## onKeyDown

## onKeyPress

## onKeyUp

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

Listing 15-41 is a working laboratory that you can use to better understand the way keyboard event codes and modifier keys work in IE5+ and NN6. The actual code of the listing is less important than watching the page while you use it. For every key or key combination that you press, the page shows the `keyCode` value for the `onKeyDown`, `onKeyPress`, and `onKeyUp` events. If you hold down one or more modifier keys while performing the key press, the modifier key name is highlighted for each of the three events. Note that when run in NN6, the `keyCode` value is not the character code (which doesn't show up in this example for NN6). Also, you may need to click the NN6 page for the `document` object to recognize the keyboard events.

The best way to watch what goes on during keyboard events is to press and hold a key to see the key codes for the `onKeyDown` and `onKeyPress` events. Then release the key to see the code for the `onKeyUp` event. Notice, for instance, that if you press the A key without any modifier key, the `onKeyDown` event key code is 65 (A) but the `onKeyPress` key code in IE (and the `charCode` property in NN6 if it were displayed here) is 97 (a). If you then repeat the exercise but hold the Shift key down, all three events generate the 65 (A) key code (and the Shift modifier labels are highlighted). Releasing the Shift key causes the `onKeyUp` event to show the key code for the Shift key.

In another experiment, press any of the four arrow keys. No key code is passed for the `onKeyPress` event because those keys don't generate those events. They do, however, generate `onKeyDown` and `onKeyUp` events.

Spend some time with this lab, and try all kinds of keys and key combinations until you understand the way the events and key codes work.

## onLoseCapture

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

See Listing 15-30 earlier in this chapter for an example of how to use `onLoseCapture` with an event-capturing scenario for displaying a context menu. The `onLoseCapture` event handler hides the context menu when the user performs any action that causes the menu to lose mouse capture.

## onMouseDown onMouseUp

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

To demonstrate a likely scenario of changing button images in response to rolling atop an image, pressing down on it, releasing the mouse button, and rolling away from the image, Listing 15-42 presents a pair of small navigation buttons (left- and right-arrow buttons). Because the image object is not part of the document object model for NN2 or IE3 (which reports itself as Navigator version 2), the page is designed to accept all browsers. Only those browsers that support precached

images and image swapping (and thus pass the test for the presence of the `document.images` array) can execute those statements. For a browser with an image object, images are preloaded into the browser cache as the page loads so that response to the user is instantaneous the first time the user calls upon new versions of the images.

### Listing 15-42: Using `onMouseDown` and `onMouseUp` Event Handlers

```
<HTML>
<HEAD>
<TITLE>onMouseDown and onMouseUp Event Handlers</TITLE>
<SCRIPT LANGUAGE="JavaScript">
if (document.images) {
 var RightNormImg = new Image(16,16)
 var RightUpImg = new Image(16,16)
 var RightDownImg = new Image(16,16)
 var LeftNormImg = new Image(16,16)
 var LeftUpImg = new Image(16,16)
 var LeftDownImg = new Image(16,16)

 RightNormImg.src = "RightNorm.gif"
 RightUpImg.src = "RightUp.gif"
 RightDownImg.src = "RightDown.gif"
 LeftNormImg.src = "LeftNorm.gif"
 LeftUpImg.src = "LeftUp.gif"
 LeftDownImg.src = "LeftDown.gif"
}
function setImage(imgName, type) {
 if (document.images) {
 var imgFile = eval(imgName + type + ".src")
 document.images[imgName].src = imgFile
 return false
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>onMouseDown and onMouseUp Event Handlers</H1>
<HR>
<P>Roll atop and click on the buttons to see how the link event handlers swap
images:</P>
<CENTER>
<A HREF="javascript:void(0)"
 onMouseOver="return setImage('Left','Up')"
 onMouseDown="return setImage('Left','Down')"
```

*Continued*

Listing 15-42 (*continued*)

```

 onMouseUp="return setImage('Left','Up')"
 onMouseOut="return setImage('Left','Norm')"
 >

<A HREF="javascript:void(0)"
 onMouseOver="return setImage('Right','Up')"
 onMouseDown="return setImage('Right','Down')"
 onMouseUp="return setImage('Right','Up')"
 onMouseOut="return setImage('Right','Norm')"
 >

</CENTER>
</BODY>
</HTML>

```

IE4+ and NN6+ simplify the implementation of this kind of three-state image button by allowing you to assign the event handlers directly to IMG element objects. Wrapping images inside links is a backward compatibility approach that allows older browsers to respond to clicks on images for navigation or other scripting tasks.

## onMouseEnter onMouseLeave

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

You can modify Listing 15-43 with the IE5.5 syntax by substituting `onMouseEnter` for `onMouseOver` and `onMouseLeave` for `onMouseOut`. The effect is the same.

## onMouseMove

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			(✓)	✓			✓	✓	✓

## Example

Listing 15-43 is a simplified example of dragging elements in IE4+. (See Chapter 31 for more dragging examples.) Three images are individually positioned on the page. Most of the scripting code concerns itself with the geography of click locations, the stacking order of the images, and the management of the `onMouseMove` event handler so that it is active only when an item is dragged.

Scripts assign the `onMouseDown` and `onMouseUp` event handlers to the document object, invoking the `engage()` and `release()` functions, respectively. When a user mouses down anywhere in the document, the `engage()` function starts by invoking `setSelectedObj()`. This function examines the target of the `mouseDown` event. If it is one of the map images, the `selectedObj` global variable is set to the image object and the element is brought to the front of the stacking order of images (any previously stacked image is returned to its normal position in the stack). `MouseDown` events on any other element simply make sure that the `selectedObj` variable is `null`. The presence of a value assigned to `selectedObj` serves as a kind of switch for other functions: When the variable contains a value, it means that the user is doing something associated with dragging an element.

Back at the `engage()` function — provided the user mouses down on one of the draggable images — the `onMouseMove` event handler is assigned to the document object, setting it to invoke the `dragIt()` function. For the sake of users, the offset of the mouse down event from the top-left corner of the image is preserved in the `offsetX` and `offsetY` variables (minus any scrolling that the body is subject to at that instant). These offset values are necessary to let the scripts set the location of the image during dragging (the location is set for the top-left corner of the image) while keeping the cursor in the same location within the image as when the user first presses the mouse.

As the user drags the image, the `onMouseDown` event handler fires repeatedly, allowing the `dragIt()` function to continually update the location of the element relative to the current cursor position (the `event.clientX` and `event.clientY` properties). The global offset variables are subtracted from the cursor position to preserve the relation of the image's top-left corner to the initial cursor position at mouse down.

Upon the user releasing the mouse button, the `release()` function turns off the `onMouseMove` event handler (setting it to `null`). This prevents the event from being processed at all during normal usage of the page. The `selectedObj` global variable is also set to `null`, turning off the “switch” that indicates dragging is in session.

## onMouseOut onMouseOver

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

Listing 15-44 uses the U.S. Pledge of Allegiance with four links to demonstrate how to use the `onmouseover` and `onmouseout` event handlers. Notice that for each link, the handler runs a general-purpose function that sets the window's status message. The function returns a true value, which the event handler call evaluates to replicate the required `return true` statement needed for setting the status bar. In one status message, I supply a URL in parentheses to let you evaluate how helpful you think it is for users.

### Listing 15-44: Using `onmouseover` and `onmouseout` Event Handlers

```
<HTML>
<HEAD>

</BODY>
</HTML>
```

## onPaste

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 15-45 demonstrates how to use the `onBeforePaste` and `onPaste` event handlers (in conjunction with `onBeforeCopy` and `onCopy`) to let scripts control the data transfer process during a copy-and-paste user operation. A table contains words to be copied (one column of nouns, one column of adjectives) and then pasted into blanks in a paragraph. The `onBeforeCopy` and `onCopy` event handlers are assigned to the `TABLE` element because the events from the `TD` elements bubble up to the `TABLE` container and there is less HTML code to contend with.

Inside the paragraph, two `SPAN` elements contain underscored blanks. To paste text into the blanks, the user must first select at least one character of the blanks. (See Listing 15-37, which gives a drag-and-drop version of this application.) The `onBeforePaste` event handler in the paragraph (which gets the event as it bubbles up from either `SPAN`) sets the `event.returnValue` property to `false`, thus allowing the Paste item to appear in the context and Edit menus (not a normal occurrence in HTML body content).

At paste time, the `innerHTML` property of the target `SPAN` is set to the text data stored in the clipboard. The `event.returnValue` property is set to `false` here, as well, to prevent normal system pasting from interfering with the controlled version.

### Listing 15-45: Using `onBeforePaste` and `onPaste` Event Handlers

```
<HTML>
<HEAD>
<TITLE>onBeforePaste and onPaste Event Handlers</TITLE>
<STYLE TYPE="text/css">
TD {text-align:center}
TH {text-decoration:underline}
.blanks {text-decoration:underline}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
```

*Continued*

## Listing 15-46 (continued)

```
function showChange() {
 var objID = event.srcElement.id
 var propName = event.propertyName
 var newValue = eval(objID + "." + propName)
 status = "The " + propName + " property of the " + objID
 status += " object has changed to \"" + newValue + "\"."
}
</SCRIPT>
</HEAD>
<BODY>
<H1>onPropertyChange Event Handler</H1>
<HR>
<P ID="myP" onPropertyChange = "showChange()">This is a sample paragraph.</P>
<FORM>
Text: <INPUT TYPE="radio" NAME="btn1" CHECKED onClick="normalText()">Normal
 <INPUT TYPE="radio" NAME="btn1" onClick="shortText()">Short

Color: <INPUT TYPE="radio" NAME="btn2" CHECKED onClick="normalColor()">Black
 <INPUT TYPE="radio" NAME="btn2" onClick="hotColor()">Red
</FORM>
</BODY>
</HTML>
```

## onReadyStateChange

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

You can use the `onReadyStateChange` event handler to assist with a status display while a long external file, such as a Java applet, loads. For example, you might have a small image on a page that changes with the state change of an applet. The `<APPLET>` tag assigns a function to the `onReadyStateChange` event handler:

```
<APPLET ... onReadyStateChange="showState(this)">
```

Then the function changes the image for each state type:

```
function showState(obj) {
 var img = document.all.statusImage
 switch (obj.readyState) {
 case "uninitialized" :
 img.src = uninit.src
 break
 case "loading" :
 img.src = loading.src
 break
 case "complete" :
 img.src = ready.src
 }
}
```

The preceding function assumes that the state images are precached as the page loads.

## onResize

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

If you want to capture the user's resizing of the browser window (or frame), you can assign a function to the `onResize` event handler either via script

```
window.onresize = handleResize
```

or by an HTML attribute of the BODY element:

```
<BODY onResize="handleResize()">
```

## onSelectStart

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use the page from Listing 15-47 to see how the `onSelectStart` event handler works when a user selects across multiple elements on a page. As the user begins a selection anywhere on the page, the ID of the object receiving the event appears in the status bar. Notice that the event doesn't fire until you actually make a selection. When no other element is under the cursor, the BODY element fires the event.

### Listing 15-47: Using the `onSelectStart` Event Handler

```
<HTML>
<HEAD>
<TITLE>onSelectStart Event Handler</TITLE>
<STYLE TYPE="text/css">
TD {text-align:center}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">

 <TD ID="cellC3">text</TD>
</TR>
</TABLE>
</BODY>
</HTML>
```

## Chapter 16 Examples

The following sections contain examples from Chapter 16, “Window and Frame Objects.”

### Window Object

#### Properties

##### `clipboardData`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

#### Example

See Listings 15-30 and 15-39 to see how the `clipboardData` object is used with a variety of edit-related event handlers.

##### `closed`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

#### Example

In Listing 16-4, I have created the ultimate cross-platform window opening and closing sample. It takes into account the lack of the `opener` property in Navigator 2, the missing `closed` property in Navigator 2 and Internet Explorer 3, and it even provides an ugly but necessary workaround for the inability of Internet Explorer 3 to gracefully see if a subwindow is still open.

The script begins by initializing a global variable, `newWind`, which is used to hold the object reference to the second window. This value needs to be global so that other functions can reference the window for tasks, such as closing. Another global

variable, `isIE3`, is a Boolean flag that lets the window closing routines know whether the visitor is using Internet Explorer 3 (see details about the `navigator.appVersion` property in Chapter 28).

For this example, the new window contains some HTML code written dynamically to it, rather than loading an existing HTML file into it. Therefore, the URL parameter of the `window.open()` method is left as an empty string. It is vital, however, to assign a name in the second parameter to accommodate the Internet Explorer 3 workaround for closing the window. After the new window is opened, an `opener` property is assigned to the object if one is not already assigned (this property is needed only for Navigator 2). Next comes a brief delay to allow Internet Explorer (especially versions 3 and 4) to catch up with opening the window so that content can be written to it. The delay (using the `setTimeout()` method described later in this chapter) invokes the `finishNewWindow()` function, which uses the global `newWind` variable to reference the window for writing. The `document.close()` method closes writing to the document—a different kind of close than a window close.

A separate function, `closeWindow()`, is responsible for closing the subwindow. To accommodate Internet Explorer 3, the script appears to create another window with the same characteristics as the one opened earlier in the script. This is the trick: If the earlier window exists (with exactly the same parameters and a name *other* than an empty string), Internet Explorer does not create a new window even with the `window.open()` method executing in plain sight. To the user, nothing unusual appears on the screen. Only if the user has closed the subwindow do things look weird for Internet Explorer 3 users. The `window.open()` method momentarily creates that subwindow. This subwindow is necessary because a “living” window object must be available for the upcoming test of window existence (Internet Explorer 3 displays a script error if you try to address a missing window, while NN2+ and IE4+ simply return friendly `null` values).

As a final test, an `if` condition looks at two conditions: 1) if the window object has ever been initialized with a value other than `null` (in case you click the window closing button before ever having created the new window) and 2) if the window’s `closed` property is `null` or `false`. If either condition is true, the `close()` method is sent to the second window.

#### Listing 16-4: Checking Before Closing a Window

```
<HTML>
<HEAD>
<TITLE>window.closed Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// initialize global var for new window object
// so it can be accessed by all functions on the page
```

```

var newWind
// set flag to help out with special handling for window closing
var isIE3 = (navigator.appVersion.indexOf("MSIE 3") != -1) ? true : false
// make the new window and put some stuff in it
function newWindow() {
 newWind = window.open("", "subwindow", "HEIGHT=200,WIDTH=200")
 // take care of Navigator 2
 if (newWind.opener == null) {
 newWind.opener = window
 }
 setTimeout("finishNewWindow()", 100)
}
function finishNewWindow() {
 var output = ""
 output += "<HTML><BODY><H1>A Sub-window</H1>"
 output += "<FORM><INPUT TYPE='button' VALUE='Close Main Window'"
 output += "onClick='window.opener.close()'></FORM></BODY></HTML>"
 newWind.document.write(output)
 newWind.document.close()
}
// close subwindow, including ugly workaround for IE3
function closeWindow() {
 if (isIE3) {
 // if window is already open, nothing appears to happen
 // but if not, the subwindow flashes momentarily (yech!)
 newWind = window.open("", "subwindow", "HEIGHT=200,WIDTH=200")
 }
 if (newWind && !newWind.closed) {
 newWind.close()
 }
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
<INPUT TYPE="button" VALUE="Open Window" onClick="newWindow()">

<INPUT TYPE="button" VALUE="Close it if Still Open" onClick="closeWindow()">
</FORM>
</BODY>
</HTML>

```

To complete the example of the window opening and closing, notice that the sub-window is given a button whose `onClick` event handler closes the main window. In Navigator 2 and Internet Explorer 3, this occurs without complaint. But in NN3+ and IE4+, the user is presented with an alert asking to confirm the closure of the main browser window.

## defaultStatus

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Unless you plan to change the default statusbar text while a user spends time at your Web page, the best time to set the property is when the document loads. In Listing 16-5, notice how I also read this property to reset the statusbar in an `onMouseOut` event handler. Setting the `status` property to empty also resets the statusbar to the `defaultStatus` setting.

### Listing 16-5: Setting the Default Status Message

```
<HTML>
<HEAD>
<TITLE>window.defaultStatus property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
window.defaultStatus = "Welcome to my Web site."
</SCRIPT>
</HEAD>
<BODY>
<A HREF="http://www.microsoft.com"
onMouseOver="window.status = 'Visit Microsoft\'s Home page.';return true"
onMouseOut="window.status = '';return true">Microsoft<P>
<A HREF="http://home.netscape.com"
onMouseOver="window.status = 'Visit Netscape\'s Home page.';return true"
onMouseOut="window.status = window.defaultStatus;return true">Netscape
</BODY>
</HTML>
```

If you need to display single or double quotes in the statusbar (as in the second link in Listing 16-5), use escape characters (`\'` and `\"`) as part of the strings being assigned to these properties.

## dialogArguments

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 16-38 for the `window.showModalDialog()` method to see how arguments can be passed to a dialog box and retrieved via the `dialogArguments` property.

## dialogHeight dialogWidth

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Dialog boxes sometimes provide a button or icon that reveals more details or more complex settings for advanced users. You can create a function that handles the toggle between two sizes. The following function assumes that the document in the dialog box has a button whose label also toggles between “Show Details” and “Hide Details.” The button’s `onClick` event handler invokes the function as `toggleDetails(this)`.

```
function toggleDetails(btn) {
 if (dialogHeight == "200px") {
 dialogHeight = "350px"
 btn.value = "Hide Details"
 } else {
 dialogHeight = "200px"
 btn.value = "Show Details"
 }
}
```

In practice, you also have to toggle the `display` style sheet property of the extra material between `none` and `block` to make sure that the dialog box does not display scrollbars in the smaller dialog box version.

## dialogLeft dialogTop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Although usually not a good idea because of the potentially jarring effect on a user, you can reposition a dialog box window that has been resized by script (or by the user if you let the dialog box be resizable). The following statements in a dialog box window document's script recenters the dialog box window.

```
dialogLeft = (screen.availWidth/2) - (parseInt(dialogWidth)/2) + "px"
dialogHeight = (screen.availHeight/2) - (parseInt(dialogHeight)/2) + "px"
```

Note that the `parseInt()` functions are used to read the numeric portion of the `dialogWidth` and `dialogHeight` properties so that the values can be used for arithmetic.

## directories locationbar menubar personalbar scrollbars statusbar toolbar

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓					

### Example

In Listing 16-6, you can experiment with the look of a browser window with any of the chrome elements turned on and off. To run this script, you must either sign the scripts or turn on codebase principals (see Chapter 46). Java must also be enabled to use the signed script statements.

As the page loads, it stores the current state of each chrome element. One button for each chrome element triggers the `toggleBar()` function. This function inverts the visible property for the chrome object passed as a parameter to the function. Finally, the Restore button returns visibility to their original settings. Notice that the `restore()` function is also called by the `onUnload` event handler for the document. Also, if you load this example into NN6, non-fatal script errors occur when the scrollbars are turned on or off.

### Listing 16-6: Controlling Window Chrome

```
<HTML>
<HEAD>
<TITLE>Bars Bars Bars</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// store original outer dimensions as page loads
var originalLocationbar = window.locationbar.visible
var originalMenubar = window.menubar.visible
var originalPersonalbar = window.personalbar.visible
var originalScrollbars = window.scrollbars.visible
var originalStatusbar = window.statusbar.visible
var originalToolbar = window.toolbar.visible

// generic function to set inner dimensions
function toggleBar(bar) {
 netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite")
 bar.visible = !bar.visible
 netscape.security.PrivilegeManager.revertPrivilege("UniversalBrowserWrite")
}
// restore settings
function restore() {
 netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite")
 window.locationbar.visible = originalLocationbar
 window.menubar.visible = originalMenubar
 window.personalbar.visible = originalPersonalbar
 window.scrollbars.visible = originalScrollbars
 window.statusbar.visible = originalStatusbar
 window.toolbar.visible = originalToolbar
 netscape.security.PrivilegeManager.revertPrivilege("UniversalBrowserWrite")
}
</SCRIPT>
</HEAD>
<BODY onUnload="restore()">
<FORM>
Toggle Window Bars

<INPUT TYPE="button" VALUE="Location Bar"
onClick="toggleBar(window.locationbar)">

<INPUT TYPE="button" VALUE="Menu Bar" onClick="toggleBar(window.menubar)">

```

*Continued*

**Listing 16-6 (continued)**

```

<INPUT TYPE="button" VALUE="Personal Bar"
onClick="toggleBar(window.personalbar)">

<INPUT TYPE="button" VALUE="Scrollbars"
onClick="toggleBar(window.scrollbars)">

<INPUT TYPE="button" VALUE="Status Bar"
onClick="toggleBar(window.statusbar)">

<INPUT TYPE="button" VALUE="Tool Bar" onClick="toggleBar(window.toolbar)">

<HR>
<INPUT TYPE="button" VALUE="Restore Original Settings" onClick="restore()">

</FORM>
</BODY>
</HTML>

```

**external**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

The first example asks the user if it is okay to add a Web site to the Active Desktop. If Active Desktop is not enabled, the user is given the choice of enabling it at this point.

```
external.AddDesktopComponent("http://www.nytimes.com","website", 200, 100,
400, 400)
```

In the next example, the user is asked to approve the addition of a URL to the Favorites list. The user can follow the normal procedure for filing the item in a folder in the list.

```
external.AddFavorite("http://www.dannyg.com/update6.html",
"JSBible 4 Support Center")
```

The final example assumes that a user makes a choice from a SELECT list of items. The onChange event handler of the SELECT list invokes the following function to navigate to a fictitious page and locate listings for a chosen sports team on the page.

```
function locate(list) {
 var choice = list.options[list.selectedIndex].value
```

```

 external.NavigateAndFind("http://www.collegesports.net/scores.html", choice,
"scores")
}

```

## frames

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listings 16-7 and 16-8 demonstrate how JavaScript treats values of frame references from objects inside a frame. The same document is loaded into each frame. A script in that document extracts info about the current frame and the entire frameset. Figure 16-5 shows the results after loading the HTML document in Listing 16-7.

#### Listing 16-7: Framesetting Document for Listing 16-8

```

<HTML>
<HEAD>
<TITLE>>window.frames property</TITLE>
</HEAD>
<FRAMESET COLS="50%,50%">
 <FRAME NAME="JustAKid1" SRC="1st16-08.htm">
 <FRAME NAME="JustAKid2" SRC="1st16-08.htm">
</FRAMESET>
</HTML>

```

A call to determine the number (`length`) of frames returns 0 from the point of view of the current frame referenced. That's because each frame here is a window that has no nested frames within it. But add the `parent` property to the reference, and the scope zooms out to take into account all frames generated by the parent window's document.

#### Listing 16-8: Showing Various Window Properties

```

<HTML>
<HEAD>
<TITLE>Window Revealer II</TITLE>

```

*Continued*

## Listing 16-8 (continued)

```

<SCRIPT LANGUAGE="JavaScript">
function gatherWindowData() {
 var msg = ""
 msg += "From the point of view of this frame:
"
 msg += "window.frames.length: " + window.frames.length + "
"
 msg += "window.name: " + window.name + "<P>"
 msg += "From the point of view of the framesetting document:
"
 msg += "parent.frames.length: " + parent.frames.length + "
"
 msg += "parent.frames[0].name: " + parent.frames[0].name
 return msg
}
</SCRIPT>
</HEAD>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
document.write(gatherWindowData())
</SCRIPT>
</BODY>
</HTML>

```

Figure 16-5: Property readouts from both frames loaded from Listing 16-7

The last statement in the example shows how to use the array syntax (brackets) to refer to a specific frame. All array indexes start with 0 for the first entry. Because the document asks for the name of the first frame (`parent.frames[0]`), the response is `JustAKid1` for both frames.

`innerHeight`  
`innerWidth`  
`outerHeight`  
`outerWidth`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓					

### Example

In Listing 16-9, a number of buttons let you see the results of setting the `innerHeight`, `innerWidth`, `outerHeight`, and `outerWidth` properties.

#### Listing 16-9: Setting Window Height and Width

```
<HTML>
<HEAD>
<TITLE>Window Sizer</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// store original outer dimensions as page loads
var originalWidth = window.outerWidth
var originalHeight = window.outerHeight
// generic function to set inner dimensions
function setInner(width, height) {
 window.innerWidth = width
 window.innerHeight = height
}
// generic function to set outer dimensions
function setOuter(width, height) {
 window.outerWidth = width
 window.outerHeight = height
}
```

*Continued*

## Listing 16-9 (continued)

```

// restore window to original dimensions
function restore() {
 window.outerWidth = originalWidth
 window.outerHeight = originalHeight
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
Setting Inner Sizes

<INPUT TYPE="button" VALUE="600 Pixels Square" onClick="setInner(600,600)">

<INPUT TYPE="button" VALUE="300 Pixels Square" onClick="setInner(300,300)">

<INPUT TYPE="button" VALUE="Available Screen Space"
onClick="setInner(screen.availWidth, screen.availHeight)">

<HR>
Setting Outer Sizes

<INPUT TYPE="button" VALUE="600 Pixels Square" onClick="setOuter(600,600)">

<INPUT TYPE="button" VALUE="300 Pixels Square" onClick="setOuter(300,300)">

<INPUT TYPE="button" VALUE="Available Screen Space"
onClick="setOuter(screen.availWidth, screen.availHeight)">

<HR>
<INPUT TYPE="button" VALUE="Cinch up for Win95" onClick="setInner(273,304)">

<INPUT TYPE="button" VALUE="Cinch up for Mac" onClick="setInner(273,304)">

<INPUT TYPE="button" VALUE="Restore Original" onClick="restore()">

</FORM>
</BODY>
</HTML>

```

As the document loads, it saves the current outer dimensions in global variables. One of the buttons restores the windows to these settings. Two parallel sets of buttons set the inner and outer dimensions to the same pixel values so that you can see the effects on the overall window and document area when a script changes the various properties.

Because Navigator 4 displays different-looking buttons in different platforms (as well as other elements), the two buttons contain script instructions to size the window to best display the window contents. Unfortunately, no measure of the active area of a document is available, so that the dimension values were determined by trial and error before being hard-wired into the script.

## navigator

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

This book is littered with examples of using the `navigator` object, primarily for performing browser detection. Examples of specific `navigator` object properties can be found in Chapter 28.

## offscreenBuffering

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

If you want to turn off buffering for an entire page, include the following statement at the beginning of your script statements:

```
window.offscreenBuffering = false
```

## onerror

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

In Listing 16-10, one button triggers a script that contains an error. I've added an error handling function to process the error so that it opens a separate window and fills in a textarea form element (see Figure 16-6). If you load Listing 16-10 in NN6, some of the reporting categories report "undefined" because the browser unfortunately does not pass error properties to the `handleError()` function. A Submit button is also

provided to mail the bug information to a support center e-mail address—an example of how to handle the occurrence of a bug in your scripts.

### Listing 16-10: Controlling Script Errors

```

<HTML>
<TITLE>Error Dialog Control</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
// function with invalid variable value
function goWrong() {
 var x = fred
}
// turn off error dialogs
function errOff() {
 window.onerror = doNothing
}
// turn on error dialogs with hard reload
function errOn() {
 window.onerror = handleError
}

// assign default error handler
window.onerror = handleError

// error handler when errors are turned off...prevents error dialog
function doNothing() {return true}

function handleError(msg, URL, lineNum) {
 var errWind = window.open("", "errors", "HEIGHT=270,WIDTH=400")
 var wintxt = "<HTML><BODY BGCOLOR=RED>"
 wintxt += "An error has occurred on this page. "
 wintxt += "Please report it to Tech Support."
 wintxt += "<FORM METHOD=POST ENCTYPE='text/plain' "
 wintxt += "ACTION=mailto:support4@dannyg.com >"
 wintxt += "<TEXTAREA NAME='errMsg' COLS=45 ROWS=8 WRAP=VIRTUAL>"
 wintxt += "Error: " + msg + "\n"
 wintxt += "URL: " + URL + "\n"
 wintxt += "Line: " + lineNum + "\n"
 wintxt += "Client: " + navigator.userAgent + "\n"
 wintxt += "-----\n"
 wintxt += "Please describe what you were doing when the error occurred:"
 wintxt += "</TEXTAREA><P>"
 wintxt += "<INPUT TYPE=SUBMIT VALUE='Send Error Report'>"
 wintxt += "<INPUT TYPE=button VALUE='Close' onClick='self.close()'>"
 wintxt += "</FORM></BODY></HTML>"
 errWind.document.write(wintxt)
 errWind.document.close()
 return true
}

```

```

</SCRIPT>
</HEAD>
<BODY>
<FORM NAME="myform">
<INPUT TYPE="button" VALUE="Cause an Error" onClick="goWrong()"><P>
<INPUT TYPE="button" VALUE="Turn Off Error Dialogs" onClick="errOff()">
<INPUT TYPE="button" VALUE="Turn On Error Dialogs" onClick="errOn()">
</FORM>
</BODY>
</HTML>

```

**Figure 16-6:** An example of a self-reporting error window

I provide a button that performs a hard reload, which, in turn, resets the `window.onerror` property to its default value. With error dialog boxes turned off, the error handling function does not run.

## opener

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓	✓	✓	✓	✓	✓

### Example

To demonstrate the importance of the `opener` property, take a look at how a new window can define itself from settings in the main window (Listing 16-11). The `doNew()` function generates a small subwindow and loads the file in Listing 16-12

into the window. Notice the initial conditional statements in `doNew()` to make sure that if the new window already exists, it comes to the front by invoking the new window's `focus()` method. You can see the results in Figure 16-7. Because the `doNew()` function in Listing 16-11 uses window methods and properties not available in IE3, this example does not work correctly in IE3.

### Listing 16-11: Contents of a Main Window Document That Generates a Second Window

```
<HTML>
<HEAD>
<TITLE>Master of all Windows</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
var myWind
function doNew() {
 if (!myWind || myWind.closed) {
 myWind = window.open("lst16-12.htm","subWindow",
 "HEIGHT=200,WIDTH=350,resizable")
 } else {
 // bring existing subwindow to the front
 myWind.focus()
 }
}
</SCRIPT>
</HEAD>
<BODY>
<FORM NAME="input">
Select a color for a new window:
<INPUT TYPE="radio" NAME="color" VALUE="red" CHECKED>Red
<INPUT TYPE="radio" NAME="color" VALUE="yellow">Yellow
<INPUT TYPE="radio" NAME="color" VALUE="blue">Blue
<INPUT TYPE="button" NAME="storage" VALUE="Make a Window" onClick="doNew()">
<HR>
This field will be filled from an entry in another window:
<INPUT TYPE="text" NAME="entry" SIZE=25>
</FORM>
</BODY>
</HTML>
```

The `window.open()` method doesn't provide parameters for setting the new window's background color, so I let the `getColor()` function in the new window do the job as the document loads. The function uses the `opener` property to find out which radio button on the main page is selected.

**Listing 16-12: References to the opener Property**

```

<HTML>
<HEAD>
<TITLE>New Window on the Block</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function getColor() {
 // shorten the reference
 colorButtons = self.opener.document.forms[0].color
 // see which radio button is checked
 for (var i = 0; i < colorButtons.length; i++) {
 if (colorButtons[i].checked) {
 return colorButtons[i].value
 }
 }
 return "white"
}
</SCRIPT>
</HEAD>
<SCRIPT LANGUAGE="JavaScript">
document.write("<BODY BGCOLOR='" + getColor() + "'>")
</SCRIPT>
<H1>This is a new window.</H1>
<FORM>
<INPUT TYPE="button" VALUE="Who's in the Main window?"
onClick="alert(self.opener.document.title)"><P>
Type text here for the main window:
<INPUT TYPE="text" SIZE=25 onChange="self.opener.document.forms[0].entry.value =
this.value">
</FORM>
</BODY>
</HTML>

```

In the `getColor()` function, the multiple references to the radio button array can be very long. To simplify the references, the `getColor()` function starts out by assigning the radio button array to a variable I arbitrarily call `colorButtons`. That shorthand now stands in for lengthy references as I loop through the radio buttons to determine which button is checked and retrieve its value property.

A button in the second window simply fetches the title of the opener window's document. Even if another document loads in the main window in the meantime, the `opener` reference still points to the main window: Its `document` object, however, will change.

Finally, the second window contains a text input object. Enter any text there that you like and either tab or click out of the field. The `onChange` event handler updates the field in the opener's document (provided that document is still loaded).

**Figure 16-7:** The main and subwindows, inextricably linked via the `window.opener` property

<b>Compatibility</b>			✓	✓					

### Example

The script in Listing 16-13 is an unusual construction that creates a frameset and creates the content for each of the two frames all within a single HTML document (see “Frame Object” later in this chapter for more details). The purpose of this example is to provide you with a playground to become familiar with the page offset concept and how the values of these properties correspond to physical activity in a scrollable document.

In the left frame of the frameset are two fields that are ready to show the pixel values of the right frame's `pageXOffset` and `pageYOffset` properties. The content of the right frame is a 30-row table of fixed width (800 pixels). Mouse click events are captured by the document level (see Chapter 18), allowing you to click any table or cell border or outside the table to trigger the `showOffsets()` function in the right frame. That function is a simple script that displays the page offset values in their respective fields in the left frame.

### Listing 16-13: Viewing the `pageXOffset` and `pageYOffset` Properties

```
<HTML>
<HEAD>
<TITLE>Master of all Windows</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function leftFrame() {
 var output = "<HTML><BODY><H3>Page Offset Values</H3><HR>\n"
 output += "<FORM>PageXOffset:<INPUT TYPE='text' NAME='xOffset'
SIZE=4>
\n"
 output += "PageYOffset:<INPUT TYPE='text' NAME='yOffset' SIZE=4>
\n"
 output += "</FORM></BODY></HTML>"
 return output
}

function rightFrame() {
 var output = "<HTML><HEAD><SCRIPT LANGUAGE='JavaScript'>\n"
 output += "function showOffsets() {\n"
 output += "parent.readout.document.forms[0].xOffset.value =
self.pageXOffset\n"
 output += "parent.readout.document.forms[0].yOffset.value =
self.pageYOffset\n}\n"
 output += "document.captureEvents(Event.CLICK)\n"
 output += "document.onclick = showOffsets\n"
 output += "<\/SCRIPT><\/HEAD><BODY><H3>Content Page<\/H3>\n"
 output += "Scroll this frame and click on a table border to view " +
 "page offset values.
<HR>\n"
 output += "<TABLE BORDER=5 WIDTH=800>"
 var oneRow = "<TD>Cell 1<\/TD><TD>Cell 2<\/TD><TD>Cell 3<\/TD><TD>Cell 4<\/TD>" +
 "<TD>Cell 5<\/TD>"
 for (var i = 1; i <= 30; i++) {
 output += "<TR><TD>Row " + i + "<\/B><\/TD>" + oneRow + "<\/TR>"
 }
 output += "<\/TABLE><\/BODY><\/HTML>"
 return output
}
<\/SCRIPT>
<\/HEAD>
```

**Listing 16-13 (continued)**

```

<FRAMESET COLS="30%,70%">
 <FRAME NAME="readout" SRC="javascript:parent.leftFrame()">
 <FRAME NAME="display" SRC="javascript:parent.rightFrame()">
</FRAMESET>
</HTML>

```

To gain an understanding of how the offset values work, scroll the window slightly in the horizontal direction and notice that the `pageXOffset` value increases; the same goes for the `pageYOffset` value as you scroll down. Remember that these values reflect the coordinate in the document that is currently under the top-left corner of the window (frame) holding the document. You can see an IE4+ version of this example in Listing 18-20. A cross-browser version would require very little browser branching.

**parent**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

To demonstrate how various `window` object properties refer to window levels in a multiframe environment, use your browser to load the Listing 16-14 document. It, in turn, sets each of two equal-size frames to the same document: Listing 16-15. This document extracts the values of several window properties, plus the `document.title` properties of two different window references.

**Listing 16-14: Framesetting Document for Listing 16-15**

### Listing 16-15: Revealing Various Window-Related Properties

```

<HTML>
<HEAD>
<TITLE>Window Revealer II</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function gatherWindowData() {
 var msg = ""
 msg = msg + "top name: " + top.name + "
"
 msg = msg + "parent name: " + parent.name + "
"
 msg = msg + "parent.document.title: " + parent.document.title + "<P>"
 msg = msg + "window name: " + window.name + "
"
 msg = msg + "self name: " + self.name + "
"
 msg = msg + "self.document.title: " + self.document.title
 return msg
}
</SCRIPT>
</HEAD>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
document.write(gatherWindowData())
</SCRIPT>
</BODY>
</HTML>

```

---

In the two frames (Figure 16-8), the references to the window and self object names return the name assigned to the frame by the frameset definition (JustAKid1 for the left frame, JustAKid2 for the right frame). In other words, from each frame's point of view, the window object is its own frame. References to self.document.title refer only to the document loaded into that window frame. But references to the top and parent windows (which are one and the same in this example) show that those object properties are shared between both frames.

**Figure 16-8:** Parent and top properties being shared by both frames.

A couple other fine points are worth highlighting. First, the name of the framesetting window is set as Listing 16-14 loads, rather than in response to an `onLoad` event handler in the `<FRAMESET>` tag. The reason for this is that the name must be set in time for the documents loading in the frames to get that value. If I had waited until the frameset's `onLoad` event handler, the name wouldn't be set until after the frame documents had loaded. Second, I restore the parent window's name to an empty string when the framesetting document unloads. This is to prevent future pages from getting confused about the window name.

## returnValue

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

See Listing 16-39 for the `showModalDialog()` method for an example of how to get data back from a dialog box in IE4+.

## screenLeft screenTop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

**Example**

Use The Evaluator (Chapter 13) to experiment with the `screenLeft` and `screenTop` properties. Start with the browser window maximized (if you are using Windows). Enter the following property name into the top text box:

```
window.screenLeft
```

Click the Evaluate button to see the current setting. Unmaximize the window and drag it around the screen. Each time you finish dragging, click the Evaluate button again to see the current value. Do the same for `window.screenTop`.

## screenX screenY

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

**Example**

Use The Evaluator (Chapter 13) to experiment with the `screenX` and `screenY` properties in NN6. Start with the browser window maximized (if you are using Windows). Enter the following property name into the top text box:

```
window.screenY
```

Click the Evaluate button to see the current setting. Unmaximize the window and drag it around the screen. Each time you finish dragging, click the Evaluate button again to see the current value. Do the same for `window.screenY`.

## scrollX

## scrollY

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `scrollX` and `scrollY` properties in NN6. Enter the following property into the top text box:

```
window.scrollToY
```

Now manually scroll the page down so that you can still see the Evaluate button. Click the button to see how far the window has scrolled along the y-axis.

## self

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listing 16-16 uses the same operations as Listing 16-5 but substitutes the `self` property for all `window` object references. The application of this reference is entirely optional, but it can be helpful for reading and debugging scripts if the HTML document is to appear in one frame of a multiframe window — especially if other JavaScript code in this document refers to documents in other frames. The `self` reference helps anyone reading the code know precisely which frame was being addressed.

#### Listing 16-16: Using the `self` Property

```
<HTML>
<HEAD>
<TITLE>self Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

self.defaultStatus = "Welcome to my Web site."
</SCRIPT>
</HEAD>
<BODY>
<A HREF="http:// www.microsoft.com"
onMouseOver="self.status = 'Visit Microsoft\'s Home page.';return true"
onMouseOut="self.status = '';return true">Microsoft<P>
<A HREF="http://home.netscape.com"
onMouseOver="self.status = 'Visit Netscape\'s Home page.';return true"
onMouseOut="self.status = self.defaultStatus;return true">Netscape
</BODY>
</HTML>

```

## status

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

In Listing 16-17, the `status` property is set in a handler embedded in the `onMouseOver` attribute of two HTML link tags. Notice that the handler requires a `return true` statement (or any expression that evaluates to `return true`) as the last statement of the handler. This statement is required or the status message will not display, particularly in early browsers.

### Listing 16-17: Links with Custom Statusbar Messages

```

<HTML>
<HEAD>
<TITLE>window.status Property</TITLE>
</HEAD>
<BODY>
<A HREF="http://www.dannyg.com" onMouseOver="window.status = 'Go to my Home
page. (www.dannyg.com)'; return true">Home<P>
<A HREF="http://home.netscape.com" onMouseOver="window.status = 'Visit Netscape
Home page. (home.netscape.com)'; return true">Netscape
</BODY>
</HTML>

```

As a safeguard against platform-specific anomalies that affect the behavior of `onMouseOver` event handlers and the `window.status` property, you should also include an `onMouseOut` event handler for links and client-side image map area objects. Such `onMouseOut` event handlers should set the `status` property to an empty string. This setting ensures that the statusbar message returns to the `defaultStatus` setting when the pointer rolls away from these objects. If you want to write a generalizable function that handles all window status changes, you can do so, but word the `onMouseOver` attribute carefully so that the event handler evaluates to return `true`. Listing 16-18 shows such an alternative.

### Listing 16-18: Handling Status Message Changes

```
<HTML>
<HEAD>
<TITLE>Generalizable window.status Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function showStatus(msg) {
 window.status = msg
 return true
}
</SCRIPT>
</HEAD>
<BODY>
<A HREF="http:// www.dannyg.com " onmouseover="return showStatus('Go to my Home
page (www.dannyg.com).')" onmouseout="return showStatus('')">Home<P>
<A HREF="http://home.netscape.com" onmouseover="return showStatus('Visit
Netscape Home page.')" onmouseout="return showStatus('')">Netscape
</BODY>
</HTML>
```

Notice how the event handlers return the results of the `showStatus()` method to the event handler, allowing the entire handler to evaluate to return `true`.

One final example of setting the statusbar (shown in Listing 16-19) also demonstrates how to create a simple scrolling banner in the statusbar.

### Listing 16-19: Creating a Scrolling Banner

```
<HTML>
<HEAD>
<TITLE>Message Scroller</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!--
```

```

var msg = "Welcome to my world..."
var delay = 150
var timerId
var maxCount = 0
var currCount = 1

function scrollMsg() {
 // set the number of times scrolling message is to run
 if (maxCount == 0) {
 maxCount = 3 * msg.length
 }
 window.status = msg
 // keep track of how many characters have scrolled
 currCount++
 // shift first character of msg to end of msg
 msg = msg.substring(1, msg.length) + msg.substring(0, 1)
 // test whether we've reached maximum character count
 if (currCount >= maxCount) {
 timerID = 0 // zero out the timer
 window.status = "" // clear the status bar
 return // break out of function
 } else {
 // recursive call to this function
 timerId = setTimeout("scrollMsg()", delay)
 }
}
// -->
</SCRIPT>
</HEAD>
<BODY onLoad="scrollMsg()">
</BODY>
</HTML>

```

---

Because the statusbar is being set by a standalone function (rather than by an `onMouseOver` event handler), you do not have to append a `return true` statement to set the status property. The `scrollMsg()` function uses more advanced JavaScript concepts, such as the `window.setTimeout()` method (covered later in this chapter) and string methods (covered in Chapter 34). To speed the pace at which the words scroll across the statusbar, reduce the value of `delay`.

Many Web surfers (myself included) don't care for these scrollers that run forever in the statusbar. Rolling the mouse over links disturbs the banner display. Scrollers can also crash earlier browsers, because the `setTimeout()` method eats application memory in Navigator 2. Use scrolling bars sparingly or design them to run only a few times after the document loads.

**Tip**

Setting the `status` property with `onMouseOver` event handlers has had a checked career along various implementations in Navigator. A script that sets the statusbar is always in competition against the browser itself, which uses the statusbar to report loading progress. When a “hot” area on a page is at the edge of a frame, many times the `onMouseOut` event fails to fire, thus preventing the statusbar from clearing itself. Be sure to torture test any such implementations before declaring your page ready for public access.

## Methods

`alert("message")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The parameter for the example in Listing 16-20 is a concatenated string. It joins together two fixed strings and the value of the browser's `navigator.appName` property. Loading this document causes the alert dialog box to appear, as shown in several configurations in Figure 16-10. The JavaScript Alert: line cannot be deleted from the dialog box in earlier browsers, nor can the title bar be changed in later browsers.

#### Listing 16-20: Displaying an Alert Dialog Box

```
<HTML>
<HEAD>
<TITLE>window.alert() Method</TITLE>
</HEAD>
<BODY>
<SCRIPT LANGUAGE="JavaScript">
alert("You are running the " + navigator.appName + " browser.")
</SCRIPT>
</BODY>
</HTML>
```

**Figure 16-10:** Results of the `alert()` method in Listing 16-20 in Internet Explorer 5 and Navigator 6 for Windows 98

## `captureEvents(eventTypeList)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

The page in Listing 16-21 is an exercise in capturing and releasing click events in the window object. Whenever the window is capturing click events, the `flash()` function runs. In that function, the event is examined so that only if the Control key is also being held down and the name of the button starts with “button” does the document background color flash red. For all click events (that is, those directed at objects on the page capable of their own `onClick` event handlers), the click is processed with the `routeEvent()` method to make sure the target buttons execute their own `onClick` event handlers.

### Listing 16-21: Capturing Click Events in the Window

```
<HTML>
<HEAD>
<TITLE>Window Event Capture</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
// function to run when window captures a click event
function flash(e) {
 if (e.modifiers = Event.CONTROL_MASK &&
 e.target.name.indexOf("button") == 0) {
```

*Continued*

## Listing 16-21 (continued)

```

 document.bgColor = "red"
 setTimeout("document.bgColor = 'white'", 500)
 }
 // let event continue to target
 routeEvent(e)
}
// default setting to capture click events
window.captureEvents(Event.CLICK)
// assign flash() function to click events captured by window
window.onclick = flash
</SCRIPT>
</HEAD>
<BODY BGCOLOR="white">
<FORM NAME="buttons">
Turn window click event capture on or off (Default is "On")<P>
<INPUT NAME="captureOn" TYPE="button" VALUE="Capture On"
onClick="window.captureEvents(Event.CLICK)">
<INPUT NAME="captureOff" TYPE="button" VALUE="Capture Off"
onClick="window.releaseEvents(Event.CLICK)">
<HR>
Ctrl+Click on a button to see if clicks are being captured by the window
(background color will flash red):<P>

<INPUT NAME="button1" TYPE="button" VALUE="Informix" onClick="alert('You
clicked on Informix.')">
<INPUT NAME="button2" TYPE="button" VALUE="Oracle" onClick="alert('You
clicked on Oracle.')">
<INPUT NAME="button3" TYPE="button" VALUE="Sybase" onClick="alert('You
clicked on Sybase.')">

</FORM>
</BODY>
</HTML>

```

When you try this page, also turn off window event capture. Now only the buttons' `onClick` event handlers execute, and the page does not flash red.

## `clearInterval(intervalIDnumber)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

## Example

See Listings 16-36 and 16-37 for an example of how `setInterval()` and `clearInterval()` are used together on a page.

## `clearTimeout(timeoutIDnumber)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The page in Listing 16-22 features one text field and two buttons (Figure 16-11). One button starts a countdown timer coded to last one minute (easily modifiable for other durations); the other button interrupts the timer at any time while it is running. When the minute is up, an alert dialog box lets you know.

### Listing 16-22: A Countdown Timer

```
<HTML>
<HEAD>
<TITLE>Count Down Timer</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!--
var running = false
var endTime = null
var timerID = null

function startTimer() {
 running = true
 now = new Date()
 now = now.getTime()
 // change last multiple for the number of minutes
 endTime = now + (1000 * 60 * 1)
 showCountDown()
}

function showCountDown() {
 var now = new Date()
 now = now.getTime()
 if (endTime - now <= 0) {
 stopTimer()
 }
}
```

*Continued*

Listing 16-22 (*continued*)

```

 alert("Time is up. Put down your pencils.")
 } else {
 var delta = new Date(endTime - now)
 var theMin = delta.getMinutes()
 var theSec = delta.getSeconds()
 var theTime = theMin
 theTime += ((theSec < 10) ? ":0" : ":") + theSec
 document.forms[0].timerDisplay.value = theTime
 if (running) {
 timerID = setTimeout("showCountDown()",1000)
 }
 }
}

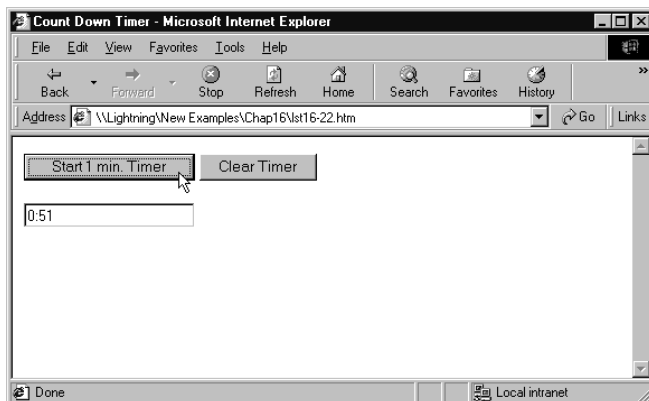

function stopTimer() {
 clearTimeout(timerID)
 running = false
 document.forms[0].timerDisplay.value = "0:00"
}
//-->
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<INPUT TYPE="button" NAME="startTime" VALUE="Start 1 min. Timer"
onClick="startTimer()">
<INPUT TYPE="button" NAME="clearTime" VALUE="Clear Timer"
onClick="stopTimer()"><P>
<INPUT TYPE="text" NAME="timerDisplay" VALUE="">
</FORM>
</BODY>
</HTML>

```

Notice that the script establishes three variables with global scope in the window: `running`, `endTime`, and `timerID`. These values are needed inside multiple functions, so they are initialized outside of the functions.

In the `startTimer()` function, you switch the `running` flag on, meaning that the timer should be going. Using some date functions (Chapter 36), you extract the current time in milliseconds and add the number of milliseconds for the next minute (the extra multiplication by one is the place where you can change the amount to the desired number of minutes). With the end time stored in a global variable, the function now calls another function that compares the current and end times and displays the difference in the text field.

**Figure 16-11:** The countdown timer page as it displays the time remaining

Early in the `showCountDown()` function, check to see if the timer has wound down. If so, you stop the timer and alert the user. Otherwise, the function continues to calculate the difference between the two times and formats the time in `mm:ss` format. As long as the `running` flag is set to `true`, the function sets the one-second timeout timer before repeating itself. To stop the timer before it has run out (in the `stopTimer()` function), the most important step is to cancel the timeout running inside the browser. The `clearTimeout()` method uses the global `timerID` value to do that. Then the function turns off the `running` switch and zeros out the display.

When you run the timer, you may occasionally notice that the time skips a second. It's not cheating. It just takes slightly more than one second to wait for the timeout and then finish the calculations for the next second's display. What you're seeing is the display catching up with the real time left.

## close()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See Listing 16-4 (for the `window.closed` property), which provides an elaborate, cross-platform, bug-accommodating example of applying the `window.close()` method across multiple windows.

```
confirm("message")
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The example in Listing 16-23 shows the user interface part of how you can use a confirm dialog box to query a user before clearing a table full of user-entered data. The line in the title bar, as shown in Figure 16-12, or the “JavaScript Confirm” legend in earlier browser versions cannot be removed from the dialog box.

### Listing 16-23: The Confirm Dialog Box

```
<HTML>
<HEAD>
<TITLE>window.confirm() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function clearTable() {
 if (confirm("Are you sure you want to empty the table?")) {
 alert("Emptying the table...") // for demo purposes
 //statements that actually empty the fields
 }
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
<!-- other statements that display and populate a large table -->
<INPUT TYPE="button" NAME="clear" VALUE="Reset Table" onClick="clearTable()">
</FORM>
</BODY>
</HTML>
```

**Figure 16-12:** A JavaScript confirm dialog box (IE5/Windows format)

## createPopup()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility									✓

### Example

See Listing 16-49 later in this chapter for an example of the `createPopup()` method.

## disableExternalCapture() enableExternalCapture()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

### Example

As this was a little-used feature of NN4 even while the browser enjoyed a substantial installed base, it becomes less important as that browser version recedes into history. You can find an example of this feature at the Support Center for this edition (<http://www.dannyg.com/update6.html>) or on pp.213–214 of the previous edition.

## execScript("exprList" [, language])

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `execScript()` method. The Evaluator has predeclared global variables for the lowercase letters a through z.

Enter each of the following statements into the top text box and observe the results for each.

a

When first loaded, the variable is declared but assigned no value, so it is undefined.

```
window.execScript("a = 5")
```

The method returns no value, so the mechanism inside The Evaluator says that the statement is undefined.

a

The variable is now 5.

```
window.execScript("b = a * 50")
```

b

The `b` global variable has a value of 250. Continue exploring with additional script statements. Use semicolons to separate multiple statements within the string parameter.

```
find(["searchString" [, matchCaseBoolean,
searchUpBoolean]])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

## Example

A simple call to the `window.find()` method looks as follows:

```
var success = window.find("contract")
```

And if you want the search to be case-sensitive, add at least one of the two optional parameters:

```
success = window.find(matchString, caseSensitive, backward)
```

Because this method works only in NN4, refer to discussions of the `TextRange` and `Range` objects in Chapter 19 for more modern implementations of body text searching.

## GetAttention()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) in NN6 to set a timer that gives you enough time to switch to another application and wait for the attention signal to fire. Enter the following statement into the top text box, click the Evaluate button, and then quickly switch to another program:

```
setTimeout("GetAttention()", 5000)
```

After a total of five seconds, the attention signal fires.

`moveBy(deltaX, deltaY)`  
`moveTo(x, y)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

Several examples of using the `window.moveTo()` and `window.moveBy()` methods are shown in Listing 16-24. The page presents four buttons, each of which performs a different kind of browser window movement.

Listing 16-24: **Window Boogie**

```

<HTML>
<HEAD>
<TITLE>Window Gymnastics</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
var isNav4 = ((navigator.appName == "Netscape") &&
(parseInt(navigator.appVersion) >= 4))
// wait in onLoad for page to load and settle in IE
function init() {
 // fill missing IE properties
 if (!window.outerWidth) {
 window.outerWidth = document.body.clientWidth
 window.outerHeight = document.body.clientHeight + 30
 }
 // fill missing IE4 properties
 if (!screen.availWidth) {
 screen.availWidth = 640
 screen.availHeight = 480
 }
}
// function to run when window captures a click event
function moveOffScreen() {
 // branch for NN security
 if (isNav4) {

netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserWrite")
 }
 var maxX = screen.width
 var maxY = screen.height
 window.moveTo(maxX+1, maxY+1)
 setTimeout("window.moveTo(0,0)",500)
 if (isNav4) {

netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserWrite")
 }
}
// moves window in a circular motion
function revolve() {
 var winX = (screen.availWidth - window.outerWidth) / 2
 var winY = 50
 window.resizeTo(400,300)
 window.moveTo(winX, winY)

 for (var i = 1; i < 36; i++) {
 winX += Math.cos(i * (Math.PI/18)) * 5
 winY += Math.sin(i * (Math.PI/18)) * 5
 window.moveTo(winX, winY)
 }
}

```

```

// moves window in a horizontal zig-zag pattern
function zigzag() {
 window.resizeTo(400,300)
 window.moveTo(0,80)
 var incrementX = 2
 var incrementY = 2
 var floor = screen.availHeight - window.outerHeight
 var rightEdge = screen.availWidth - window.outerWidth
 for (var i = 0; i < rightEdge; i += 2) {
 window.moveBy(incrementX, incrementY)
 if (i%60 == 0) {
 incrementY = -incrementY
 }
 }
}
// resizes window to occupy all available screen real estate
function maximize() {
 window.moveTo(0,0)
 window.resizeTo(screen.availWidth, screen.availHeight)
}
</SCRIPT>
</HEAD>
<BODY onLoad="init()">
<FORM NAME="buttons">
Window Gymnastics<P>

<INPUT NAME="offscreen" TYPE="button" VALUE="Disappear a Second"
onClick="moveOffScreen()">
<INPUT NAME="circles" TYPE="button" VALUE="Circular Motion"
onClick="revolve()">
<INPUT NAME="bouncer" TYPE="button" VALUE="Zig Zag" onClick="zigzag()">
<INPUT NAME="expander" TYPE="button" VALUE="Maximize" onClick="maximize()">

</FORM>
</BODY>
</HTML>

```

To run successfully in NN, the first button requires that you have codebase principals turned on (see Chapter 46) to take advantage of what would normally be a signed script. The `moveOffScreen()` function momentarily moves the window entirely out of view. Notice how the script determines the size of the screen before deciding where to move the window. After the journey off screen, the window comes back into view at the upper-left corner of the screen.

If using the Web sometimes seems like going around in circles, then the second function, `revolve()`, should feel just right. After reducing the size of the window and positioning it near the top center of the screen, the script uses a bit of math to position the window along 36 places around a perfect circle (at 10-degree increments).

This is an example of how to control a window's position dynamically based on math calculations. IE complicates the job a bit by not providing properties that reveal the outside dimensions of the browser window.

To demonstrate the `moveBy()` method, the third function, `zigzag()`, uses a `for` loop to increment the coordinate points to make the window travel in a saw tooth pattern across the screen. The `x` coordinate continues to increment linearly until the window is at the edge of the screen (also calculated on the fly to accommodate any size monitor). The `y` coordinate must increase and decrease as that parameter changes direction at various times across the screen.

In the fourth function, you see some practical code (finally) that demonstrates how best to simulate maximizing the browser window to fill the entire available screen space on the visitor's monitor.

`navigate("URL")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>					✓	✓	✓	✓	✓

### Example

Supply any valid URL as the parameter to the method, as in

```
window.navigate("http://www.dannyg.com")
```

`open("URL", "windowName" [, "windowFeatures" ][, replaceFlag])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The page rendered by Listing 16-26 displays a single button that generates a new window of a specific size that has only the statusbar turned on. The script here shows all the elements necessary to create a new window that has all the right stuff on most platforms. The new window object reference is assigned to a global variable, `newWindow`. Before a new window is generated, the script looks to see if the

window has never been generated before (in which case `newWindow` would be `null`) or, for newer browsers, the window is closed. If either condition is true, the window is created with the `open()` method. Otherwise, the existing window is brought forward with the `focus()` method (NN3+ and IE4+).

As a safeguard against older browsers, the script manually adds an `opener` property to the new window if one is not already assigned by the `open()` method. The current window object reference is assigned to that property.

Due to the timing problem that afflicts all IE generations, the HTML assembly and writing to the new window is separated into its own function that is invoked after a 50 millisecond delay (NN goes along for the ride, but it could accommodate the assembly and writing without the delay). To build the string that is eventually written to the document, I use the `+=` (add-by-value) operator, which appends the string on the right side of the operator to the string stored in the variable on the left side. In this example, the new window is handed an `<H1>`-level line of text to display.

### Listing 16-26: Creating a New Window

```
<HTML>
<HEAD>
<TITLE>New Window</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var newWindow
function makeNewWindow() {
 if (!newWindow || newWindow.closed) {
 newWindow = window.open("", "", "status,height=200,width=300")
 if (!newWindow.opener) {
 newWindow.opener = window
 }
 // force small delay for IE to catch up
 setTimeout("writeToWindow()", 50)
 } else {
 // window's already open; bring to front
 newWindow.focus()
 }
}
function writeToWindow() {
 // assemble content for new window
 var newContent = "<HTML><HEAD><TITLE>One Sub Window</TITLE></HEAD>"
 newContent += "<BODY><H1>This window is brand new.</H1>"
 newContent += "</BODY></HTML>"
 // write HTML to new window document
 newWindow.document.write(newContent)
 newWindow.document.close() // close layout stream
}
```

*Continued*

## Listing 16-26 (continued)

```

</SCRIPT>
</HEAD>
<BODY>
<FORM>
<INPUT TYPE="button" NAME="newOne" VALUE="Create New Window"
 onClick="makeNewWindow()">
</FORM>
</BODY>
</HTML>

```

If you need to create a new window for the lowest common denominator of scriptable browser, you will have to omit the `focus()` method and the `window.closed` property from the script (as well as add the NN2 bug workaround described earlier). Or you may prefer to forego a subwindow for all browsers below a certain level. See Listing 16-3 (in the `window.closed` property discussion) for other ideas about cross-browser authoring for subwindows.

## print()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓				✓	✓

## Example

Listing 16-27 is a frameset that loads Listing 16-28 into the top frame and a copy of the Bill of Rights into the bottom frame.

## Listing 16-27: Print Frameset

```

<HTML>
<HEAD>
<TITLE>window.print() method</TITLE>
</HEAD>
<FRAMESET ROWS="25%,75%">
 <FRAME NAME="controls" SRC="lst16-28.htm">
 <FRAME NAME="display" SRC="bofright.htm">
</FRAMESET>
</HTML>

```

Two buttons in the top control panel (Listing 16-28) let you print the whole frameset (in those browsers and OSes that support it) or just the lower frame. To print the entire frameset, the reference includes the parent window; to print the lower frame, the reference is directed at the `parent.display` frame.

### Listing 16-28: Printing Control

```
<HTML>
<HEAD>
<TITLE>Print()</TITLE>
</HEAD>
<BODY>
<FORM>
<INPUT TYPE="button" NAME="printWhole" VALUE="Print Entire Frameset"
onClick="parent.print()"><P>
<INPUT TYPE="button" NAME="printFrame" VALUE="Print Bottom Frame Only"
onClick="parent.display.print()"><P>
</FORM>
</BODY>
</HTML>
```

If you don't like some facet of the printed output, blame the browser's print engine, and not JavaScript. The `print()` method merely invokes the browser's regular printing routines. Pages whose content is generated entirely by JavaScript print only in NN3+ and IE4+.

`prompt("message", "defaultReply")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The function that receives values from the prompt dialog box in Listing 16-29 (see the dialog box in Figure 16-13) does some data-entry validation (but certainly not enough for a commercial site). The function first checks to make sure that the returned value is neither `null` (Cancel) nor an empty string (the user clicked OK without entering any values). See Chapter 43 for more about data-entry validation.

### Listing 16-29: The Prompt Dialog Box

```

<HTML>
<HEAD>
<TITLE>window.prompt() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function populateTable() {
 var howMany = prompt("Fill in table for how many factors?","")
 if (howMany != null && howMany != "") {
 alert("Filling the table for " + howMany) // for demo
 //statements that validate the entry and
 //actually populate the fields of the table
 }
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
<!-- other statements that display and populate a large table -->
<INPUT TYPE="button" NAME="fill" VALUE="Fill Table..."
onClick="populateTable()">
</FORM>
</BODY>
</HTML>

```

**Figure 16-13:** The prompt dialog box displayed from Listing 16-29 (Windows format)

Notice one important user interface element in Listing 16-29. Because clicking the button leads to a dialog box that requires more information from the user, the button's label ends in an ellipsis (or, rather, three periods acting as an ellipsis character). The ellipsis is a common courtesy to let users know that a user interface element leads to a dialog box of some sort. As in similar situations in Windows and Macintosh programs, the user should be able to cancel out of that dialog box and return to the same screen state that existed before the button was clicked.

```
resizeBy(deltaX,deltaY)
resizeTo(outerwidth,outerheight)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

You can experiment with the `resize` methods with the page in Listing 16-30. Two parts of a form let you enter values for each method. The one for `window.resize()` also lets you enter a number of repetitions to better see the impact of the values. Enter zero and negative values to see how those affect the method. Also test the limits of different browsers.

#### Listing 16-30: Window Resize Methods

```
<HTML>
<HEAD>
<TITLE>Window Resize Methods</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function doResizeBy(form) {
 var x = parseInt(form.resizeByX.value)
 var y = parseInt(form.resizeByY.value)
 var count = parseInt(form.count.value)
 for (var i = 0; i < count; i++) {
 window.resizeBy(x, y)
 }
}
function doResizeTo(form) {
 var x = parseInt(form.resizeToX.value)
 var y = parseInt(form.resizeToY.value)
 window.resizeTo(x, y)
}
</SCRIPT>
</HEAD>
<BODY>
<FORM>
Enter the x and y increment, plus how many times the window should be resized
by these increments:

Horiz:<INPUT TYPE="text" NAME="resizeByX" SIZE=4>
Vert:<INPUT TYPE="text" NAME="resizeByY" SIZE=4>
How Many:<INPUT TYPE="text" NAME="count" SIZE=4>
```

*Continued*

**Listing 16-30 (continued)**

```

<INPUT TYPE="button" NAME="ResizeBy" VALUE="Show resizeBy()"
onClick="doResizeBy(this.form)">
<HR>
Enter the desired width and height of the current window:

Width:<INPUT TYPE="text" NAME="resizeToX" SIZE=4>
Height:<INPUT TYPE="text" NAME="resizeToY" SIZE=4>
<INPUT TYPE="button" NAME="ResizeTo" VALUE="Show resizeTo()"
onClick="doResizeTo(this.form)">
</FORM>
</BODY>
</HTML>

```

**routeEvent(*event*)**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

**Example**

The `window.routeEvent()` method is used in the example for `window.captureEvents()`, Listing 16-21.

**scroll(*horizontalCoord*, *verticalCoord*)**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

**Example**

To demonstrate the `scroll()` method, Listing 16-31 defines a frameset with a document in the top frame (Listing 16-32) and a control panel in the bottom frame (Listing 16-33). A series of buttons and text fields in the control panel frame directs the scrolling of the document. I've selected an arbitrary, large GIF image to use in

the example. To see results of some horizontal scrolling values, you may need to shrink the width of the browser window until a horizontal scrollbar appears in the top frame. If you substitute `scrollTo()` for the `scroll()` methods in Listing 16-33, the results will be the same, but you will need version browsers at a minimum to run it.

### Listing 16-31: A Frameset for the scroll() Demonstration

```
<HTML>
<HEAD>
<TITLE>window.scroll() Method</TITLE>
</HEAD>

<FRAMESET ROWS="50%,50%">
 <FRAME SRC="1st16-32.htm" NAME="display">
 <FRAME SRC="1st16-33.htm" NAME="control">
</FRAMESET>
</HTML>
```

---

### Listing 16-32: The Image to Be Scrolled

```
<HTML>
<HEAD>
<TITLE>Arch</TITLE>
</HEAD>

<BODY>
<H1>A Picture is Worth...</H1>
<HR>
<CENTER>
<TABLE BORDER=3>
<CAPTION ALIGN=bottom>A Splendid Arch</CAPTION>
<TD>

</TD></TABLE></CENTER>
</BODY>
</HTML>
```

---

**Listing 16-33: Controls to Adjust Scrolling of the Upper Frame**

```

<HTML>
<HEAD>
<TITLE>Scroll Controller</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
function scroll(x,y) {
 parent.frames[0].scroll(x,y)
}
function customScroll(form) {
 parent.frames[0].scroll(parseInt(form.x.value),parseInt(form.y.value))
}
</SCRIPT>
</HEAD>
<BODY>
<H2>Scroll Controller</H2>
<HR>
<FORM NAME="fixed">
Click on a scroll coordinate for the upper frame:<P>
<INPUT TYPE="button" VALUE="0,0" onClick="scroll(0,0)">
<INPUT TYPE="button" VALUE="0,100" onClick="scroll(0,100)">
<INPUT TYPE="button" VALUE="100,0" onClick="scroll(100,0)">
<P>
<INPUT TYPE="button" VALUE="-100,100" onClick="scroll(-100,100)">
<INPUT TYPE="button" VALUE="20,200" onClick="scroll(20,200)">
<INPUT TYPE="button" VALUE="1000,3000" onClick="scroll(1000,3000)">
</FORM>
<HR>
<FORM NAME="custom">
Enter a Horizontal
<INPUT TYPE="text" NAME="x" VALUE="0" SIZE=4>
and Vertical
<INPUT TYPE="text" NAME="y" VALUE="0" SIZE=4>
value. Then
<INPUT TYPE="button" VALUE="click to scroll" onClick="customScroll(this.form)">
</FORM>
</BODY>
</HTML>

```

Notice that in the `customScroll()` function, JavaScript must convert the string values from the two text boxes to integers (with the `parseInt()` method) for the `scroll()` method to accept them. Nonnumeric data can produce very odd results. Also be aware that although this example shows how to adjust the scroll values in another frame, you can set such values in the same frame or window as the script, as well as in subwindows, provided that you use the correct object references to the window.

```
scrollBy(deltaX,deltaY)
scrollTo(x,y)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

To work with the `scrollTo()` method, you can use Listings 16-31 through 16-33 (the `window.scroll()` method) but substitute `window.scrollTo()` for `window.scroll()`. The results should be the same. For `scrollBy()`, the example starts with the frameset in Listing 16-34. It loads the same content document as the `window.scroll()` example (Listing 16-32), but the control panel (Listing 16-35) provides input to experiment with the `scrollBy()` method.

#### Listing 16-34: Frameset for ScrollBy Controller

```
<HTML>
<HEAD>
<TITLE>window.scrollBy() Method</TITLE>
</HEAD>

<FRAMESET ROWS="50%,50%">
 <FRAME SRC="1st16-32.htm" NAME="display">
 <FRAME SRC="1st16-35.htm" NAME="control">
</FRAMESET>
</HTML>
```

Notice in Listing 16-35 that all references to window properties and methods are directed to the `display` frame. String values retrieved from text fields are converted to number with the `parseInt()` global function.

#### Listing 16-35: ScrollBy Controller

```
<HTML>
<HEAD>
<TITLE>ScrollBy Controller</TITLE>
```

*Continued*

## Listing 16-35 (continued)

```

<SCRIPT LANGUAGE="JavaScript1.2">
function page(direction) {
 var pixFrame = parent.display
 var deltaY = (pixFrame.innerHeight) ? pixFrame.innerHeight :
 pixFrame.document.body.scrollHeight
 if (direction == "up") {
 deltaY = -deltaY
 }
 parent.display.scrollBy(0, deltaY)
}
function customScroll(form) {
 parent.display.scrollBy(parseInt(form.x.value), parseInt(form.y.value))
}
</SCRIPT>
</HEAD>
<BODY>
ScrollBy Controller
<FORM NAME="custom">
Enter an Horizontal increment

and Vertical
<INPUT TYPE="text" NAME="y" VALUE="0" SIZE=4">
value.
Then
<INPUT TYPE="button" VALUE="click to scrollBy()"
onClick="customScroll(this.form)">
<HR>
<INPUT TYPE="button" VALUE="PageDown" onClick="page('down')">
<INPUT TYPE="button" VALUE="PageUp" onClick="page('up')">

</FORM>
</BODY>
</HTML>

```

`setCursor("cursorType")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

## Example

Use The Evaluator (Chapter 13) in NN6 to experiment with setting the cursor. After clicking the top text box in preparation for typing, roll the cursor to a location atop an empty spot on the page. Then enter the following statements one at a time into the top text box, and press Enter/Return:

```
setCursor("wait")
setCursor("spinning")
setCursor("move")
```

After evaluating each statement, roll the cursor around the page, and notice where the cursor reverts to its normal appearance.

```
setInterval("expr", msecDelay [, language])
setInterval(funcRef, msecDelay [, funcarg1,
..., funcargn])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

## Example

The demonstration of the `setInterval()` method entails a two-framed environment. The framesetting document is shown in Listing 16-36.

### Listing 16-36: `setInterval()` Demonstration Frameset

```
<HTML>
<HEAD>
<TITLE>setInterval() Method</TITLE>
</HEAD>

<FRAMESET ROWS="50%,50%">
 <FRAME SRC="1st16-37.htm" NAME="control">
 <FRAME SRC="bofright.htm" NAME="display">
</FRAMESET>
</HTML>
```

In the top frame is a control panel with several buttons that control the automatic scrolling of the Bill of Rights text document in the bottom frame. Listing 16-37 shows the control panel document. Many functions here control the interval, scrolling jump size, and direction, and they demonstrate several aspects of applying `setInterval()`.

Notice that in the beginning the script establishes a number of global variables. Three of them are parameters that control the scrolling; the last one is for the ID value returned by the `setInterval()` method. The script needs that value to be a global value so that a separate function can halt the scrolling with the `clearInterval()` method.

All scrolling is performed by the `autoScroll()` function. For the sake of simplicity, all controlling parameters are global variables. In this application, placement of those values in global variables helps the page restart autoscrolling with the same parameters as it had when it last ran.

### Listing 16-37: `setInterval()` Control Panel

```
<HTML>
<HEAD>
<TITLE>ScrollBy Controller</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
var scrollSpeed = 500
var scrollJump = 1
var scrollDirection = "down"
var intervalID

function autoScroll() {
 if (scrollDirection == "down") {
 scrollJump = Math.abs(scrollJump)
 } else if (scrollDirection == "up" && scrollJump > 0) {
 scrollJump = -scrollJump
 }
 parent.display.scrollBy(0, scrollJump)
 if (parent.display.pageYOffset <= 0) {
 clearInterval(intervalID)
 }
}

function reduceInterval() {
 stopScroll()
 scrollSpeed -= 200
 startScroll()
}
function increaseInterval() {
```

```

 stopScroll()
 scrollSpeed += 200
 startScroll()
 }
 function reduceJump() {
 scrollJump -= 2
 }
 function increaseJump() {
 scrollJump += 2
 }
 function swapDirection() {
 scrollDirection = (scrollDirection == "down") ? "up" : "down"
 }
 function startScroll() {
 parent.display.scrollBy(0, scrollJump)
 if (intervalID) {
 clearInterval(intervalID)
 }
 intervalID = setInterval("autoScroll()",scrollSpeed)
 }
 function stopScroll() {
 clearInterval(intervalID)
 }
</SCRIPT>
</HEAD>
<BODY onLoad="startScroll()">
AutoScroll by setInterval() Controller
<FORM NAME="custom">
<INPUT TYPE="button" VALUE="Start Scrolling" onClick="startScroll()">
<INPUT TYPE="button" VALUE="Stop Scrolling" onClick="stopScroll()"><P>
<INPUT TYPE="button" VALUE="Shorter Time Interval" onClick="reduceInterval()">
<INPUT TYPE="button" VALUE="Longer Time Interval"
onClick="increaseInterval()"><P>
<INPUT TYPE="button" VALUE="Bigger Scroll Jumps" onClick="increaseJump()">
<INPUT TYPE="button" VALUE="Smaller Scroll Jumps" onClick="reduceJump()"><P>
<INPUT TYPE="button" VALUE="Change Direction" onClick="swapDirection()">

</FORM>
</BODY>
</HTML>

```

The `setInterval()` method is invoked inside the `startScroll()` function. This function initially “burps” the page by one `scrollJump` interval so that the test in `autoScroll()` for the page being scrolled all the way to the top doesn’t halt a page from scrolling before it gets started. Notice, too, that the function checks for the existence of an interval ID. If one is there, it is cleared before the new one is set. This is crucial within the design of the example page, because repeated clicking of the Start Scrolling button triggers multiple interval timers inside the browser. Only

the most recent one's ID would be stored in `intervalID`, allowing no way to clear the older ones. But this little side trip makes sure that only one interval timer is running. One of the global variables, `scrollSpeed`, is used to fill the delay parameter for `setInterval()`. To change this value on the fly, the script must stop the current interval process, change the `scrollSpeed` value, and start a new process.

The intensely repetitive nature of this application is nicely handled by the `setInterval()` method.

```
setTimeout("expr", msecDelay [, language])
setTimeout(functionRef, msecDelay [, funcarg1,
..., funcargn])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

When you load the HTML page in Listing 16-38, it triggers the `updateTime()` function, which displays the time (in hh:mm am/pm format) in the statusbar. Instead of showing the seconds incrementing one by one (which may be distracting to someone trying to read the page), this function alternates the last character of the display between an asterisk and nothing, like a visual “heartbeat.”

### Listing 16-38: Display the Current Time

```
<HTML>
<HEAD>
<TITLE>Status Bar Clock</TITLE>
<SCRIPT LANGUAGE="JavaScript">
<!--
var flasher = false
// calculate current time, determine flasher state,
// and insert time into status bar every second
function updateTime() {
 var now = new Date()
 var theHour = now.getHours()
 var theMin = now.getMinutes()
 var theTime = "" + ((theHour > 12) ? theHour - 12 : theHour)
 theTime += ((theMin < 10) ? ":0" : ":") + theMin
 theTime += (theHour >= 12) ? " pm" : " am"
 theTime += ((flasher) ? " " : "**")
```

```

 flasher = !flasher
 window.status = theTime
 // recursively call this function every second to keep timer going
 timerID = setTimeout("updateTime()",1000)
}
//-->
</SCRIPT>
</HEAD>

<BODY onLoad="updateTime()">
</BODY>
</HTML>

```

In this function, the `setTimeout()` method works in the following way: Once the current time (including the flasher status) appears in the statusbar, the function waits approximately one second (1,000 milliseconds) before calling the same function again. You don't have to clear the `timerID` value in this application because JavaScript does it for you every time the 1,000 milliseconds elapse.

A logical question to ask is whether this application should be using `setInterval()` instead of `setTimeout()`. This is a case in which either one does the job. To use `setInterval()` here would require that the interval process start outside of the `updateTime()` function, because you need only one process running that repeatedly calls `updateTime()`. It would be a cleaner implementation in that regard, instead of the tons of timeout processes spawned by Listing 16-38. On the other hand, the application would not run in any browsers before NN4 or IE4, as Listing 16-38 does.

To demonstrate passing parameters, you can modify the `updateTime()` function to add the number of times it gets invoked to the display in the statusbar. For that to work, the function must have a parameter variable so that it can catch a new value each time it is invoked by `setTimeout()`'s expression. For all browsers, the function would be modified as follows (unchanged lines are represented by the ellipsis):

```

function updateTime(i) {
 ...
 window.status = theTime + " (" + i + ")"
 // pass updated counter value with next call to this function
 timerID = setTimeout("updateTime(" + i+1 + ")",1000)
}

```

If you were running this exclusively in NN4+, you could use its more convenient way of passing parameters to the function:

```

timerID = setTimeout(updateTime,1000, i+1)

```

In either case, the `onLoad` event handler would also have to be modified to get the ball rolling with an initial parameter:

```
onLoad = "updateTime(0)"
```

One warning about `setTimeout()` functions that dive into themselves as frequently as this one does: Each call eats up a bit more memory for the browser application in Navigator 2. If you let this clock run for a while, some browsers may encounter memory difficulties, depending on which operating system they're using. But considering the amount of time the typical user spends on Web pages (even if only 10 or 15 minutes), the function shouldn't present a problem. And any reloading invoked by the user (such as by resizing the window in Navigator 2) frees up memory once again.

```
showModalDialog("URL"[, arguments]
[, features])
showModelessDialog("URL"[, arguments]
[, features])
```

### Example

To demonstrate the two styles of dialog boxes, I have implemented the same functionality (setting some session visual preferences) for both modal and modeless dialog boxes. This tactic shows you how to pass data back and forth between the main page and both styles of dialog box windows.

The first example demonstrates how to use a modal dialog box. In the process, data is passed into the dialog box window and values are returned. Listing 16-39 is the HTML and scripting for the main page. A button's `onClick` event handler invokes a function that opens the modal dialog box. The dialog box's document (Listing 16-40) contains several form elements for entering a user name and selecting a few color styles for the main page. Data from the dialog is fashioned into an array to be sent back to the main window. That array is initially assigned to a local variable, `prefs`, as the dialog box closes. If the user cancels the dialog box, the returned value is an empty string, so nothing more in `getPrefsData()` executes. But when the user clicks OK, the array comes back. Each of the array items is read and assigned to its respective form value or style property. These values are also preserved in the global `currPrefs` array. This allows the settings to be sent to the modal dialog box (as the second parameter to `showModalDialog()`) the next time the dialog box is opened.

**Listing 16-39: Main Page for showModalDialog()**

```

<HTML>
<HEAD>
<TITLE>window.setModalDialog() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var currPrefs = new Array()
function getPrefsData() {
 var prefs = showModalDialog("1st16-40.htm", currPrefs,
 "dialogWidth:400px; dialogHeight:300px")
 if (prefs) {
 if (prefs["name"]) {
 document.all.firstName.innerText = prefs["name"]
 currPrefs["name"] = prefs["name"]
 }
 if (prefs["bgColor"]) {
 document.body.style.backgroundColor = prefs["bgColor"]
 currPrefs["bgColor"] = prefs["bgColor"]
 }
 if (prefs["textColor"]) {
 document.body.style.color = prefs["textColor"]
 currPrefs["textColor"] = prefs["textColor"]
 }
 if (prefs["h1Size"]) {
 document.all.welcomeHeader.style.fontSize = prefs["h1Size"]
 currPrefs["h1Size"] = prefs["h1Size"]
 }
 }
}
function init() {
 document.all.firstName.innerText = "friend"
}
</SCRIPT>

</HEAD>
<BODY BGCOLOR="#e0e0e0" STYLE="margin:20px" onLoad="init()">
<H1>window.setModalDialog() Method</H1>
<HR>
<H2 ID="welcomeHeader">Welcome, !</H2>
<HR>
<P>Use this button to set style preferences for this page:
<BUTTON ID="prefsButton" onClick="getPrefsData()">
Preferences
</BUTTON>
</BODY>
</HTML>

```

The dialog box's document, shown in Listing 16-40, is responsible for reading the incoming data (and setting the form elements accordingly) and assembling form data for return to the main window's script. Notice when you load the example that the TITLE element of the dialog box's document appears in the dialog box window's title bar.

When the page loads into the dialog box window, the `init()` function examines the `window.dialogArguments` property. If it has any data, the data is used to pre-set the form elements to mirror the current settings of the main page. A utility function, `setSelected()`, pre-selects the option of a SELECT element to match the current settings.

Buttons at the bottom of the page are explicitly positioned to be at the lower-right corner of the window. Each button invokes a function to do what is needed to close the dialog box. In the case of the OK button, the `handleOK()` function sets the `window.returnValue` property to the data that come back from the `getFormData()` function. This latter function reads the form element values and packages them in an array using the form elements' names as array indices. This helps keep everything straight back in the main window's script, which uses the index names, and is therefore not dependent upon the precise sequence of the form elements in the dialog box window.

### Listing 16-40: Document for the Modal Dialog

```
<HTML>
<HEAD>
<TITLE>User Preferences</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// Close the dialog
function closeme() {
 window.close()
}

// Handle click of OK button
function handleOK() {
 window.returnValue = getFormData()
 closeme()
}

// Handle click of Cancel button
function handleCancel() {
 window.returnValue = ""
 closeme()
}
// Generic function converts form element name-value pairs
// into an array
```

```

function getFormData() {
 var form = document.prefs
 var returnedData = new Array()
 // Harvest values for each type of form element
 for (var i = 0; i < form.elements.length; i++) {
 if (form.elements[i].type == "text") {
 returnedData[form.elements[i].name] = form.elements[i].value
 } else if (form.elements[i].type.indexOf("select") != -1) {
 returnedData[form.elements[i].name] =
 form.elements[i].options[form.elements[i].selectedIndex].value
 } else if (form.elements[i].type == "radio") {
 returnedData[form.elements[i].name] = form.elements[i].value
 } else if (form.elements[i].type == "checkbox") {
 returnedData[form.elements[i].name] = form.elements[i].value
 } else continue
 }
 return returnedData
}
// Initialize by setting form elements from passed data
function init() {
 if (window.dialogArguments) {
 var args = window.dialogArguments
 var form = document.prefs
 if (args["name"]) {
 form.name.value = args["name"]
 }
 if (args["bgColor"]) {
 setSelected(form.bgColor, args["bgColor"])
 }
 if (args["textColor"]) {
 setSelected(form.textColor, args["textColor"])
 }
 if (args["h1Size"]) {
 setSelected(form.h1Size, args["h1Size"])
 }
 }
}
// Utility function to set a SELECT element to one value
function setSelected(select, value) {
 for (var i = 0; i < select.options.length; i++) {
 if (select.options[i].value == value) {
 select.selectedIndex = i
 break
 }
 }
 return
}
// Utility function to accept a press of the
// Enter key in the text field as a click of OK

```

*Continued*

## Listing 16-40 (continued)

```

function checkEnter() {
 if (window.event.keyCode == 13) {
 handleOK()
 }
}
</SCRIPT>
</HEAD>

<BODY BGCOLOR="#e0e0e0" onLoad="init()">
<H2>Web Site Preferences</H2>

</TR>
</TABLE>
</FORM>
<DIV STYLE="position:absolute; left:200px; top:220px">
<BUTTON STYLE="width:80px" onClick="handleOK()">OK</BUTTON>
<BUTTON STYLE="width:80px" onClick="handleCancel()">Cancel</BUTTON>
</DIV>
</BODY>
</HTML>

```

One last convenience feature of the dialog box window is the `onKeyPress` event handler in the text box. The function it invokes looks for the Enter key. If that key is pressed while the box has focus, the same `handleOK()` function is invoked, as if the user had clicked the OK button. This feature makes the dialog box behave as if the OK button is an automatic default, just as “real” dialog boxes.

You should observe several important structural changes that were made to turn the modal approach into a modeless one. Listing 16-41 shows the version of the main window modified for use with a modeless dialog box. Another global variable, `prefsDialog`, is initialized to eventually store the reference to the modeless window returned by the `showModelessDialog()` method. The variable gets used to invoke the `init()` function inside the modeless dialog box, but also as conditions in an `if` construction surrounding the generation of the dialog box. The reason this is needed is to prevent multiple instances of the dialog box being created (the button is still alive while the modeless window is showing). The dialog box won't be created again as long as there is a value in `prefsDialog`, and the dialog box window has not been closed (picking up the `window.closed` property of the dialog box window).

The `showModelessDialog()` method's second parameter is a reference to the function in the main window that updates the main document. As you see in a moment, that function is invoked from the dialog box when the user clicks the OK or Apply buttons.

### Listing 16-41: Main Page for `showModelessDialog()`

```

<HTML>
<HEAD>
<TITLE>window.setModelessDialog() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var currPrefs = new Array()

```

*Continued*

*windowObject.showModalDialog()*

## Listing 16-41 (continued)

```

var prefsDlog
function getPrefsData() {
 if (!prefsDlog || prefsDlog.closed) {
 prefsDlog = showModelessDialog("1st16-42.htm", setPrefs,
 "dialogWidth:400px; dialogHeight:300px")
 prefsDlog.init(currPrefs)
 }
}

function setPrefs(prefs) {
 if (prefs["bgColor"]) {
 document.body.style.backgroundColor = prefs["bgColor"]
 currPrefs["bgColor"] = prefs["bgColor"]
 }
 if (prefs["textColor"]) {
 document.body.style.color = prefs["textColor"]
 currPrefs["textColor"] = prefs["textColor"]
 }
 if (prefs["h1Size"]) {
 document.all.welcomeHeader.style.fontSize = prefs["h1Size"]
 currPrefs["h1Size"] = prefs["h1Size"]
 }
 if (prefs["name"]) {
 document.all.firstName.innerText = prefs["name"]
 currPrefs["name"] = prefs["name"]
 }
}

function init() {
 document.all.firstName.innerText = "friend"
}
</SCRIPT>

</HEAD>
<BODY BGCOLOR="#e0e0e0" STYLE="margin:20px" onLoad="init()">
<H1>window.setModelessDialog() Method</H1>
<HR>
<H2 ID="welcomeHeader">Welcome, !</H2>
<HR>
<P>Use this button to set style preferences for this page:
<BUTTON ID="prefsButton" onClick="getPrefsData()">
Preferences
</BUTTON>
</BODY>
</HTML>

```

Changes to the dialog box window document for a modeless version (Listing 16-42) are rather limited. A new button is added to the bottom of the screen for an Apply button. As in many dialog box windows you see in Microsoft products, the Apply button lets current settings in dialog boxes be applied to the current document but without closing the dialog box. This approach makes experimenting with settings easier.

The Apply button invokes a `handleApply()` function, which works the same as `handleOK()`, except the dialog box is not closed. But these two functions communicate back to the main window differently than a modal dialog box. The main window's processing function is passed as the second parameter of `showModelessDialog()` and is available as the `window.dialogArguments` property in the dialog box window's script. That function reference is assigned to a local variable in both functions, and the remote function is invoked, passing the results of the `getFormData()` function as parameter values back to the main window.

### Listing 16-42: Document for the Modeless Dialog Box

```
<HTML>
<HEAD>
<TITLE>User Preferences</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// Close the dialog
function closeme() {
 window.close()
}

// Handle click of OK button
function handleOK() {
 var returnFunc = window.dialogArguments
 returnFunc(getFormData())
 closeme()
}

// Handle click of Apply button
function handleApply() {
 var returnFunc = window.dialogArguments
 returnFunc(getFormData())
}

// Handle click of Cancel button
function handleCancel() {
 window.returnValue = ""
 closeme()
}
// Generic function converts form element name-value pairs
// into an array
```

*Continued*

## Listing 16-42 (continued)

```
function getFormData() {
 var form = document.prefs
 var returnedData = new Array()
 // Harvest values for each type of form element
 for (var i = 0; i < form.elements.length; i++) {
 if (form.elements[i].type == "text") {
 returnedData[form.elements[i].name] = form.elements[i].value
 } else if (form.elements[i].type.indexOf("select") != -1) {
 returnedData[form.elements[i].name] =
 form.elements[i].options[form.elements[i].selectedIndex].value
 } else if (form.elements[i].type == "radio") {
 returnedData[form.elements[i].name] = form.elements[i].value
 } else if (form.elements[i].type == "checkbox") {
 returnedData[form.elements[i].name] = form.elements[i].value
 } else continue
 }
 return returnedData
}

// Initialize by setting form elements from passed data
function init(currPrefs) {
 if (currPrefs) {
 var form = document.prefs
 if (currPrefs["name"]) {
 form.name.value = currPrefs["name"]
 }
 if (currPrefs["bgColor"]) {
 setSelected(form.bgColor, currPrefs["bgColor"])
 }
 if (currPrefs["textColor"]) {
 setSelected(form.textColor, currPrefs["textColor"])
 }
 if (currPrefs["h1Size"]) {
 setSelected(form.h1Size, currPrefs["h1Size"])
 }
 }
}

// Utility function to set a SELECT element to one value
function setSelected(select, value) {
 for (var i = 0; i < select.options.length; i++) {
 if (select.options[i].value == value) {
 select.selectedIndex = i
 break
 }
 }
 return
}
```

```

// Utility function to accept a press of the
// Enter key in the text field as a click of OK

</DIV>
</BODY>
</HTML>

```

The biggest design challenge you probably face with respect to these windows is deciding between a modal and modeless dialog box style. Some designers insist that modality has no place in a graphical user interface; others say that there are times when you need to focus the user on a very specific task before any further processing can take place. That's where a modal dialog box makes perfect sense.

## sizeToContent()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

**Example**

Use The Evaluator (Chapter 13) in NN6 to try the `sizeToContent()` method. Assuming that you are running The Evaluator from the `Chap13` directory on the CD-ROM (or the directory copied as-is to your hard disk), you can open a subwindow with one of the other files in the directory, and then size the subwindow. Enter the following statements into the top text box:

```

a = window.open("1st13-02.htm", "")
a.sizeToContent()

```

The resized subwindow is at the minimum recommended width for a browser window, and at a height tall enough to display the little bit of content in the document.

## Event handlers

onAfterPrint  
onBeforePrint

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

The following script fragment assumes that the page includes a DIV element whose style sheet includes a setting of `display:none` as the page loads. Somewhere in the Head, the print-related event handlers are set as properties:

```
function showPrintCopyright() {
 document.all.printCopyright.style.display = "block"
}
function hidePrintCopyright() {
 document.all.printCopyright.style.display = "none"
}
window.onbeforeprint = showPrintCopyright
window.onafterprint = hidePrintCopyright
```

onBeforeUnload

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The simple page in Listing 16-43 shows you how to give the user a chance to stay on the page.

#### Listing 16-43: Using the onBeforeUnload Event Handler

```
<HTML>
<HEAD>
<TITLE>onBeforeUnload Event Handler</TITLE>
```

*Continued*

*windowObject.onBeforeUnload*

**Listing 16-43 (continued)**

```

<SCRIPT LANGUAGE="JavaScript">
function verifyClose() {
 event.returnValue = "We really like you and hope you will stay longer."
}
window.onbeforeunload = verifyClose
</SCRIPT>

</HEAD>
<BODY>
<H1>onBeforeUnload Event Handler</H1>
<HR>
<P>Use this button to navigate to the previous page:
<BUTTON ID="go" onClick="history.back()">
Go Back
</BUTTON>
</BODY>
</HTML>

```

## onHelp

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The following script fragment can be embedded in the IE5-only modeless dialog box code in Listing 16-44 to provide context-sensitive help within the dialog box. Help messages for only two of the form elements are shown here, but in a real application you add messages for the rest.

```

function showHelp() {
 switch (event.srcElement.name) {
 case "bgColor" :
 alert("Choose a color for the main window\'s background.")
 break
 case "name" :
 alert("Enter your first name for a friendly greeting.")
 break
 default :
 alert("Make preference settings for the main page styles.")
 }
}

```

```

 event.returnValue = false
 }
 window.onhelp = showHelp

```

Because this page's help focuses on form elements, the `switch` construction cases are based on the `name` properties of the form elements. For other kinds of pages, the `id` properties may be more appropriate.

## FRAME Element Object

### Properties

#### `borderColor`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Although you may experience problems (especially in IE5) changing the color of a single frame border, the W3C DOM syntax would look like the following if the script were inside the framesetting document:

```
document.getElementById("contentsFrame").borderColor = "red"
```

The IE-only version would be:

```
document.all["contentsFrame"].borderColor = "red"
```

These examples assume the frame name arrives to a script function as a string. If the script is executing in one of the frames of the frameset, add a reference to `parent` in the preceding statements.

#### `contentDocument`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

A framesetting document script might be using the ID of a FRAME element to read or adjust one of the element properties, and then need to perform some action on the content of the page through its document object. You can get the reference to the document object via a statement, such as the following:

```
var doc = document.getElementById("FRAME3").contentDocument
```

Then your script can, for example, dive into a form in the document:

```
var val = doc.mainForm.entry.value
```

## Document

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

While you have far easier ways to reach the document object of another frame (parent.otherFrameName.document), the following statement takes the long way to get there to retrieve the number of forms in the document of another frame:

```
var formCount = parent.document.all.contentsFrame.Document.forms.length
```

Using the Document property only truly makes sense when a function is passed a FRAME or IFRAME element object reference as a parameter, and the script must, among other things more related to those objects, access the document contained by those elements.

## frameBorder

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The default value for the frameBorder property is yes. You can use this setting to create a toggle script (which, unfortunately, does not change the appearance in IE). The W3C-compatible version looks like the following:

```
function toggleFrameScroll(frameID) {
 var theFrame = document.getElementById(frameID)
 if (theFrame.frameBorder == "yes") {
 theFrame.frameBorder = "no"
 } else {
 theFrame.frameBorder = "yes"
 }
}
```

## height width

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The following fragment assumes a frameset defined with two frames set up as two columns within the frameset. The statements here live in the framesetting document. They retrieve the current width of the left frame and increase the width of that frame by ten percent. Syntax shown here is for the W3C DOM, but can be easily adapted to IE-only terminology.

```
var frameWidth = document.getElementById("leftFrame").width
document.getElementById("mainFrameset").cols = (Math.round(frameWidth * 1.1)) +
",*"
```

Notice how the numeric value of the existing frame width is first increased by ten percent and then concatenated to the rest of the string property assigned to the frameset's `cols` property. The asterisk after the comma means that the browser should figure out the remaining width and assign it to the right-hand frame.

## noResize

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

The following statement turns off the ability for a frame to be resized:

```
parent.document.getElementById("myFrame1").noResize = true
```

Because of the negative nature of the property name, it may be difficult to keep the logic straight (setting `noResize` to `true` means that `resizability` is turned off). Keep a watchful eye on your Boolean values.

## scrolling

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Listing 16-45 produces a frameset consisting of eight frames. The content for the frames is generated by a script within the frameset (via the `fillFrame()` function). Event handlers in the Body of each frame invoke the `toggleFrameScroll()` function. Both ways of referencing the FRAME element object are shown, with the IE-only version commented out.

In the `toggleFrameScroll()` function, the `if` condition checks whether the property is set to something other than `no`. This allows the condition to evaluate to `true` if the property is set to either `auto` (the first time) or `yes` (as set by the function). Note that the scrollbars don't disappear from the frames in IE5.5 or NN6.

### Listing 16-45: Controlling the FRAME.scrolling Property

```
<HTML>
<HEAD>
<TITLE>frame.scrolling Property</TITLE>
</HEAD>
<SCRIPT LANGUAGE="JavaScript">
function toggleFrameScroll(frameID) {
 // IE5 & NN6 version
 var theFrame = document.getElementById(frameID)
 // IE4+ version
 // var theFrame = document.all[frameID]

 if (theFrame.scrolling != "no") {
 theFrame.scrolling = "no"
 }
}
```

```

 } else {
 theFrame.scrolling = "yes"
 }
}
// generate content for each frame
function fillFrame(frameID) {
 var page = "<HTML><BODY onClick='parent.toggleFrameScroll(\"" +
 frameID + "\")'>"
 page += "<P>This frame has the ID of:</P><P>" + frameID + ".</P>"
 page += "</BODY></HTML>"
 return page
}
</SCRIPT>

 <FRAME ID="myFrame3" SRC="javascript:parent.fillFrame('myFrame3')">
 <FRAME ID="myFrame4" SRC="javascript:parent.fillFrame('myFrame4')">
 </FRAMESET>
 <FRAMESET ID="innerFrameset2" ROWS="25%,25%,25%,25%">
 <FRAME ID="myFrame5" SRC="javascript:parent.fillFrame('myFrame5')">
 <FRAME ID="myFrame6" SRC="javascript:parent.fillFrame('myFrame6')">
 <FRAME ID="myFrame7" SRC="javascript:parent.fillFrame('myFrame7')">
 <FRAME ID="myFrame8" SRC="javascript:parent.fillFrame('myFrame8')">
 </FRAMESET>
</FRAMESET>
</HTML>

```

## src

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

For best results, use fully formed URLs as value for the `src` property, as shown here:

```
parent.document.getElementById("mainFrame").src = "http://www.dannyg.com"
```

Relative URLs and `javascript:` pseudo-URLs will also work most of the time.

# FRAMESET Element Object

## Properties

### border

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Even though the property is read/write in IE4+, changing the value does not change the thickness of the border you see in the browser. If you need to find the thickness of the border, a script reference from one of the frame's documents would look like the following:

```
var thickness = parent.document.all.outerFrameset.border
```

### borderColor

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

To retrieve the current color setting in a frameset, a script reference from one of the frame's documents would look like the following:

```
var borderColor = parent.document.all.outerFrameset.borderColor
```

### cols rows

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Listings 16-46 through 16-48 show the HTML for a frameset and two of the three documents that go into the frameset. The final document is an HTML version of the U.S. Bill of Rights, which is serving here as a content frame for the demonstration.

The frameset listing (16-46) shows a three-frame setup. Down the left column is a table of contents (16-47). The right column is divided into two rows. In the top row is a simple control (16-48) that hides and shows the table of contents frame. As the user clicks the hot text of the control (located inside a SPAN element), the `onClick` event handler invokes the `toggleTOC()` function in the frameset.

Syntax used in this example is W3C-compatible. To modify this for IE-only, you **replace** `document.getElementById("outerFrameset")` with `document.all.outerFrameset` and `elem.firstChild.nodeValue` to `elem.innerText`. You can also branch within the scripts to accommodate both styles.

### Listing 16-46: Frameset and Script for Hiding/Showing a Frame

```
<HTML>
<HEAD>
<TITLE>Hide/Show Frame Example</TITLE>
</HEAD>
<SCRIPT LANGUAGE="JavaScript">
var origCols
function toggleTOC(elem, frm) {
 if (origCols) {
 showTOC(elem)
 } else {
 hideTOC(elem, frm)
 }
}
function hideTOC(elem, frm) {
 var frameset = document.getElementById("outerFrameset")
 origCols = frameset.cols
 frameset.cols = "0,*"
}
function showTOC(elem) {
 if (origCols) {
 document.getElementById("outerFrameset").cols = origCols
 origCols = null
 }
}
</SCRIPT>
```

*Continued*

**Listing 16-46 (continued)**

```

<FRAMESET ID="outerFrameset" FRAMEBORDER="no" COLS="150,*">
 <FRAME ID="TOC" NAME="TOCFrame" SRC="1st16-47.htm">
 <FRAMESET ID="innerFrameset1" ROWS="80,*">
 <FRAME ID="controls" NAME="controlsFrame" SRC="1st16-48.htm">
 <FRAME ID="content" NAME="contentFrame" SRC="bofright.htm">
 </FRAMESET>
</FRAMESET>
</HTML>

```

When a user clicks the hot spot to hide the frame, the script copies the original `cols` property settings to a global variable. The variable is used in `showTOC()` to restore the frameset to its original proportions. This allows a designer to modify the HTML for the frameset without also having to dig into scripts to hard-wire the restored size.

**Listing 16-47: Table of Contents Frame Content**

```

<HTML>
<HEAD>

Article IX
Article X

</BODY>
</HTML>

```

**Listing 16-48: Control Panel Frame**

```

<HTML>
<HEAD>
<TITLE>Control Panel</TITLE>
</HEAD>
<BODY>
<P>
<SPAN ID="tocToggle"
 STYLE="text-decoration:underline; cursor:hand"
 onClick="parent.toggleTOC(this)"> <<Hide/Show>>
Table of Contents
</P>
</BODY>
</HTML>

```

**frameBorder**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

The default value for the `frameBorder` property is `yes`. You can use this setting to create a toggle script (which, unfortunately, does not change the appearance in IE). The IE4+-compatible version looks like the following:

```

function toggleFrameScroll(framesetID) {
 var theFrameset = document.all(framesetID)
 if (theFrameset.frameBorder == "yes") {
 theFrameset.frameBorder = "no"
 } else {
 theFrameset.frameBorder = "yes"
 }
}

```

**frameSpacing**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Even though the property is read/write in IE4+, changing the value does not change the thickness of the frame spacing you see in the browser. If you need to find the spacing as set by the tag's attribute, a script reference from one of the frame's documents would look like the following:

```
var spacing = parent.document.all.outerFrameset.frameSpacing
```

## IFRAME Element Object

### Properties

#### align

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The default setting for an IFRAME alignment is `baseline`. A script can shift the IFRAME to be flush with the right edge of the containing element as follows:

```
document.getElementById("iframe1").align = "right"
```

#### contentDocument

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

A document script might be using the ID of an IFRAME element to read or adjust one of the element properties; it then needs to perform some action on the content of the page through its `document` object. You can get the reference to the `document` object via a statement, such as the following:

```
var doc = document.getElementById("FRAME3").contentDocument
```

Then your script can, for example, dive into a form in the document:

```
var val = doc.mainForm.entry.value
```

## frameBorder

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

See the example for the `FRAME.frameBorder` property earlier in this chapter.

## hspace vspace

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The following fragment sets the white space surrounding an `IFRAME` element to an equal amount:

```
document.all.myIframe.hspace = 20
document.all.myIframe.vspace = 20
```

Unfortunately these changes do not work for IE5/Windows.

## scrolling

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The following `toggleIFrameScroll()` function accepts a string of the `IFRAME` element's ID as a parameter and switches between on and off scroll bars in the

**IFRAME.** The `if` condition checks whether the property is set to something other than `no`. This test allows the condition to evaluate to true if the property is set to either `auto` (the first time) or `yes` (as set by the function).

```
function toggleFrameScroll(frameID) {
 // IE5 & NN6 version
 var theFrame = document.getElementById(frameID)
 // IE4+ version
 // var theFrame = document.all[frameID]
 if (theFrame.scrolling != "no") {
 theFrame.scrolling = "no"
 } else {
 theFrame.scrolling = "yes"
 }
}
```

`src`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

For best results, use fully formed URLs as value for the `src` property, as shown here:

```
document.getElementById("myIframe").src = "http://www.dannyg.com"
```

Relative URLs and `javascript:` pseudo-URLs also work most of the time.

## popup Object

### Properties

`document`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `popup` object and its properties. Enter the following statements into the top text box. The first statement creates a pop-up window, whose reference is assigned to the `a` global variable. Next, a reference to the body of the pop-up's document is preserved in the `b` variable for the sake of convenience. Further statements work with these two variables.

```
a = window.createPopup()
b = a.document.body
b.style.border = "solid 2px black"
b.style.padding = "5px"
b.innerHTML = "<P>Here is some text in a popup window</P>"
a.show(200,100, 200, 50, document.body)
```

See the description of the `show()` method for details on the parameters.

## isOpen

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `isOpen` property. Enter the following statements into the top text box. The sequence begins with a creation of a simple pop-up window, whose reference is assigned to the `a` global variable. Note that the final statement is actually two statements, designed so that the second statement executes while the pop-up window is still open.

```
a = window.createPopup()
a.document.body.innerHTML = "<P>Here is a popup window</P>"
a.show(200,100, 200, 50, document.body); alert("Popup is open:" + a.isOpen)
```

If you then click into the main window to hide the pop-up, you will see a different result if you enter the following statement into the top text box by itself:

```
alert("Popup is open:" + a.isOpen)
```

## Methods

```
hide()
show(left, top, width, height
[, positioningElementRef])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>									✓

### Example

Listing 16-49 demonstrates both the `show()` and `hide()` methods for a `popup` object. A click of the button on the page invokes the `selfTimer()` function, which acts as the main routine for this page. The goal is to produce a pop-up window that “self-destructs” five seconds after it appears. Along the way, a message in the pop-up counts down the seconds.

A reference to the pop-up window is preserved as a global variable, called `popup`. After the `popup` object is created, the `initContent()` function stuffs the content into the pop-up by way of assigning `style` properties and some `innerHTML` for the body of the document that is automatically created when the pop-up is generated. A `SPAN` element is defined so that another function later on can modify the content of just that segment of text in the pop-up. Notice that the assignment of content to the pop-up is predicated on the pop-up window having been initialized (by virtue of the `popup` variable having a value assigned to it) and that the pop-up window is not showing. While invoking `initContent()` under any other circumstances is probably impossible, the validation of the desired conditions is good programming practice.

Back in `selfTimer()`, the `popup` object is displayed. Defining the desired size requires some trial and error to make sure the pop-up window comfortably accommodates the text that is put into the pop-up in the `initContent()` function.

With the pop-up window showing, now is the time to invoke the `countDown()` function. Before the function performs any action, it validates that the pop-up has been initialized and is still visible. If a user clicks the main window while the counter is counting down, this changes the value of the `isOpen` property to `false`, and nothing inside the `if` condition executes.

This `countDown()` function grabs the inner text of the `SPAN` and uses `parseInt()` to extract just the integer number (using base 10 numbering, because we’re dealing with zero-leading numbers that can potentially be regarded as octal values). The condition of the `if` construction decreases the retrieved integer by one. If the

decremented value is zero, then the time is up, and the pop-up window is hidden with the `popup` global variable returned to its original, `null` value. But if the value is other than zero, then the inner text of the SPAN is set to the decremented value (with a leading zero), and the `setTimeout()` method is called upon to reinvoke the `countDown()` function in one second (1000 milliseconds).

### Listing 16-49: Hiding and Showing a Pop-up

```

<HTML>
<HEAD>
<TITLE>popup Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var popup
function initContent() {
 if (popup && !popup.isOpen) {
 var popBody = popup.document.body
 popBody.style.border = "solid 3px red"
 popBody.style.padding = "10px"
 popBody.style.fontSize = "24pt"
 popBody.style.textAlign = "center"
 var bodyText = "<P>This popup will self-destruct in "
 bodyText += "05"
 bodyText += " seconds...</P>"
 popBody.innerHTML = bodyText
 }
}
function countDown() {
 if (popup && popup.isOpen) {
 var currCount = parseInt(popup.document.all.counter.innerText, 10)
 if (--currCount == 0) {
 popup.hide()
 popup = null
 } else {
 popup.document.all.counter.innerText = "0" + currCount
 setTimeout("countDown()", 1000)
 }
 }
}
function selfTimer() {
 popup = window.createPopup()
 initContent()
 popup.show(200,200,400,100,document.body)
 setTimeout("countDown()", 1000)
}
</SCRIPT>
</HEAD>
<BODY>

```

*Continued*

**Listing 16-49 (continued)**

```

<FORM>
<INPUT TYPE="button" VALUE="Impossible Mission" onClick="selfTimer()">
</FORM>
</BODY>
</HTML>

```

The `hide()` method here is invoked by a script that is running while the pop-up window is showing. Because a pop-up window automatically goes away if a user clicks the main window, it is highly unlikely that the `hide()` method would ever be invoked by itself in response to user action in the main window. If you want a script in the pop-up window to close the pop-up, use `parentWindow.close()`.

## Chapter 17 Examples

The following sections contain examples from Chapter 17, “Location and History Objects.”

## Location Object

### Properties

hash

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

When you load the script in Listing 17-1, adjust the size of the browser window so only one section is visible at a time. When you click a button, its script navigates to the next logical section in the progression and eventually takes you back to the top.

**Listing 17-1: A Document with Anchors**

```

<HTML>
<HEAD>
<TITLE>location.hash Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function goNextAnchor(where) {
 window.location.hash = where
}
</SCRIPT>
</HEAD>

<BODY>

<H1>Top</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="NEXT" onClick="goNextAnchor('sec1')">
</FORM>
<HR>
<H1>Section 1</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="NEXT" onClick="goNextAnchor('sec2')">
</FORM>
<HR>
<H1>Section 2</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="NEXT" onClick="goNextAnchor('sec3')">
</FORM>
<HR>
<H1>Section 3</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="BACK TO TOP"
onClick="goNextAnchor('start')">
</FORM>

</BODY>
</HTML>

```

Anchor names are passed as parameters with each button's `onClick` event handler. Instead of going through the work of assembling a `window.location` value in the function by appending a literal hash mark and the value for the anchor, here I simply modify the `hash` property of the current window's location. This is the preferred, cleaner method.

If you attempt to read back the `window.location.hash` property in an added line of script, however, the window's actual URL probably will not have been updated yet, and the browser will appear to be giving your script false information. To prevent this

problem in subsequent statements of the same function, construct the URLs of those statements from the same variable values you use to set the `window.location.hash` property—don't rely on the browser to give you the values you expect.

## host

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Use the documents in Listings 17-2 through 17-4 as tools to help you learn the values that the various `window.location` properties return. In the browser, open the file for Listing 17-2. This file creates a two-frame window. The left frame contains a temporary placeholder (Listing 17-4) that displays some instructions. The right frame has a document (Listing 17-3) that enables you to load URLs into the left frame and get readings on three different windows available: the parent window (which creates the multiframe window), the left frame, and the right frame.

#### Listing 17-2: Frameset for the Property Picker

```

>= 4) ? true : false
```

```

function fillLeftFrame() {
 newURL = prompt("Enter the URL of a document to show in the left frame:", "");
 if (newURL != null && newURL != "") {
 parent.frames[0].location = newURL
 }
}

function showLocationData(form) {
 for (var i = 0; i <3; i++) {
 if (form.whichFrame[i].checked) {
 var windName = form.whichFrame[i].value
 break
 }
 }
 var theWind = "" + windName + ".location"
 if (isNav4) {
 netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserRead")
 }
 var theObj = eval(theWind)
 form.windName.value = windName
 form.windHash.value = theObj.hash
 form.windHost.value = theObj.host
 form.windHostname.value = theObj.hostname
 form.windHref.value = theObj.href
 form.windPath.value = theObj.pathname
 form.windPort.value = theObj.port
 form.windProtocol.value = theObj.protocol
 form.windSearch.value = theObj.search
 if (isNav4) {
 netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserRead")
 }
}

</BODY>
</HTML>

```

Figure 17-1 shows the dual-frame browser window with the left frame loaded with a page from my Web site.

**Figure 17-1:** Browser window loaded to investigate window.location properties

For the best results, open a URL to a Web document on the network from the same domain and server from which you load the listings (perhaps your local hard disk). If possible, load a document that includes anchor points to navigate through a long document. Click the Left frame radio button, and then click the button that shows all properties. This action fills the table in the right frame with all the available location properties for the selected window. Figure 17-2 shows the complete results for a page from my Web site that is set to an anchor point.

Attempts to retrieve these properties from URLs outside of your domain and server result in a variety of responses based on your browser and browser version. NN2 returns null values for all properties. NN3 presents an "access disallowed" security

alert. With codebase principals turned on in NN4 (see Chapter 46), the proper values appear in their fields. IE3 does not have the same security restrictions that Navigator does, so all values appear in their fields. But in IE4+, you get a “permission denied” error alert. See the following discussion for the meanings of the other listed properties and instructions on viewing their values.

Window:	parent.frames[0]
hash:	#Computer Press Association Boc
host:	www.dannyg.com
hostname:	www.dannyg.com
href:	http://www.dannyg.com/credits.htm
pathname:	/credits.html
port:	
protocol:	http:
search:	

**Figure 17-2:** Readout of all window.location properties for the left frame

## hostname

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See Listings 17-2 through 17-4 earlier in this chapter for a set of related pages to help you view the hostname data for a variety of other pages.

## href

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

Listing 17-5 includes the `unescape()` function in front of the part of the script that captures the URL. This function serves cosmetic purposes by displaying the pathname in alert dialog boxes for browsers that normally display the ASCII-encoded version.

### Listing 17-5: Extracting the Directory of the Current Document

```
<HTML>
<HEAD>
<TITLE>Extract pathname</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// general purpose function to extract URL of current directory
function getDirPath(URL) {
 var result = unescape(URL.substring(0,(URL.lastIndexOf("/") + 1))
 return result
}
// handle button event, passing work onto general purpose function
function showDirPath(URL) {
 alert(getDirPath(URL))
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<INPUT TYPE="button" VALUE="View directory URL"
onClick="showDirPath(window.location.href)">
</FORM>
</BODY>
</HTML>
```

## pathname

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

See Listings 17-2 through 17-4 earlier in this chapter for a multiple-frame example you can use to view the `location.pathname` property for a variety of URLs of your choice.

**port**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

If you have access to URLs containing port numbers, use the documents in Listings 17-2 through 17-4 to experiment with the output of the `location.port` property.

**protocol**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

See Listings 17-2 through 17-4 for a multiple-frame example you can use to view the `location.protocol` property for a variety of URLs. Also try loading an FTP site to see the `location.protocol` value for that type of URL.

**search**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

As mentioned in the opening of Chapter 16 about frames, you can force a particular HTML page to open inside the frameset for which it is designed. But with the help of the search string, you can reuse the same framesetting document to accommodate

any number of content pages that go into one of the frames (rather than specifying a separate frameset for each possible combination of pages in the frameset). The listings in this section create a simple example of how to force a page to load in a frameset by passing some information about the page to the frameset. Thus, if a user has a URL to one of the content frames (perhaps it has been bookmarked by right-clicking the frame or it comes up as a search engine result), the page appears in its designated frameset the next time the user visits the page.

The fundamental task going on in this scheme has two parts. The first is in each of the content pages where a script checks whether the page is loaded inside a frameset. If the frameset is missing, then a search string is composed and appended to the URL for the framesetting document. The framesetting document has its own short script that looks for the presence of the search string. If the string is there, then the script extracts the search string data and uses it to load that specific page into the content frame of the frameset.

Listing 17-6 is the framesetting document. The `getSearchAsArray()` function is more complete than necessary for this simple example, but you can use it in other instances to convert any number of name/value pairs passed in the search string (in traditional format of `name1=value1&name2=value2&etc.`) into an array whose indexes are the names (making it easier for scripts to extract a specific piece of passed data). Version branching takes place because, for convenience, the `getSearchAsArray()` function uses text and array methods that don't exist in browsers prior to NN3 or IE4.

### Listing 17-6: A Smart Frameset

```
<HTML>
<HEAD>
<TITLE>Example Frameset</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// Convert location.search into an array of values
// indexed by name.
function getSearchAsArray() {
 var minNav3 = (navigator.appName == "Netscape" &&
parseInt(navigator.appVersion) >= 3)
 var minIE4 = (navigator.appName.indexOf("Microsoft") >= 0 &&
parseInt(navigator.appVersion) >= 4)
 var minDOM = minNav3 || minIE4 // baseline DOM required for this function
 var results = new Array()
 if (minDOM) {
 var input = unescape(location.search.substr(1))
 if (input) {
 var srchArray = input.split("&")
 var tempArray = new Array()
 for (var i = 0; i < srchArray.length; i++) {
```

*Continued*

**Listing 17-6 (continued)**

```

 tempArray = srchArray[i].split("=")
 results[tempArray[0]] = tempArray[1]
 }
}
return results
}
function loadFrame() {
 if (location.search) {
 var srchArray = getSearchAsArray()
 if (srchArray["content"]) {
 self.content.location.href = srchArray["content"]
 }
 }
}
</SCRIPT>
</HEAD>
<FRAMESET COLS="250,*" onLoad="loadFrame()">
 <FRAME NAME="toc" SRC="1st17-07.htm">
 <FRAME NAME="content" SRC="1st17-08.htm">
</FRAMESET>
</HTML>

```

Listing 17-7 is the HTML for the table of contents frame. Nothing elaborate goes on here, but you can see how normal navigation works for this simplified frameset.

**Listing 17-7: The Table of Contents**

```

<HTML>
<HEAD>
<TITLE>Table of Contents</TITLE>
</HEAD>
<BODY BGCOLOR="#eeeeee">
<H3>Table of Contents</H3>
<HR>

Page 1
Page 2
Page 3

</BODY>
</HTML>

```

Listing 17-8 shows one of the content pages. As the page loads, the `checkFrameset()` function is invoked. If the window does not load inside a frameset, then the script navigates to the framesetting page, passing the current content URL as a search string. Notice that for browsers that support the `location.replace()` method, the loading of this page on its own does not get recorded to the browser's history and isn't accessed if the user hits the Back button.

### Listing 17-8: A Content Page

```
<HTML>
<HEAD>
<TITLE>Page 1</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function checkFrameset() {
 var minNav3 = (navigator.appName == "Netscape" &&
parseInt(navigator.appVersion) >= 3)
 var minIE4 = (navigator.appName.indexOf("Microsoft") >= 0 &&
parseInt(navigator.appVersion) >= 4)
 var minDOM = minNav3 || minIE4 // baseline DOM required for this function
 var isNav4 = (navigator.appName == "Netscape" &&
parseInt(navigator.appVersion) == 4)
 if (parent == window) {
 // Don't do anything if running NN4
 // so that the frame can be printed on its own
 if (isNav4 && window.innerWidth == 0) {
 return
 }
 if (minDOM) {
 // Use replace() to keep current page out of history
 location.replace("lst17-06.htm?content=" + escape(location.href))
 } else {
 location.href = " lst17-06.htm?content=" + escape(location.href)
 }
 }
}
// Invoke the function
checkFrameset()
</SCRIPT>
</HEAD>
<BODY>
<H1>Page 1</H1>
<HR>
</BODY>
</HTML>
```

In practice, I recommend placing the code for the `checkFrameset()` function and call to it inside an external `.js` library and linking that library into each content document of the frameset. That's why the function assigns the generic `location.href` property to the search string—you can use it on any content page.

## Methods

`reload(unconditionalGETBoolean)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

To experience the difference between the two loading styles, load the document in Listing 17-9. Click a radio button, enter some new text, and make a choice in the SELECT object. Clicking the Soft Reload/Refresh button invokes a method that reloads the document as if you had clicked the browser's Reload/Refresh button. It also preserves the visible properties of form elements. The Hard Reload button invokes the `location.reload()` method, which resets all objects to their default settings.

#### Listing 17-9: Hard versus Soft Reloading

```
<HTML>
<HEAD>
<TITLE>Reload Comparisons</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
function hardReload() {
 location.reload(true)
}
function softReload() {
 history.go(0)
}
</SCRIPT>
</HEAD>
<BODY>
<FORM NAME="myForm">
<INPUT TYPE="radio" NAME="rad1" VALUE = 1>Radio 1

<INPUT TYPE="radio" NAME="rad1" VALUE = 2>Radio 2

<INPUT TYPE="radio" NAME="rad1" VALUE = 3>Radio 3<P>
<INPUT TYPE="text" NAME="entry" VALUE="Original"><P>
<SELECT NAME="theList">
<OPTION>Red
```

```

<OPTION>Green
<OPTION>Blue
</SELECT>
<HR>
<INPUT TYPE="button" VALUE="Soft Reload" onClick="softReload()">
<INPUT TYPE="button" VALUE="Hard Reload" onClick="hardReload()">
</FORM>
</BODY>
</HTML>

```

## replace("URL")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

Calling the `location.replace()` method navigates to another URL similarly to assigning a URL to the location. The difference is that the document doing the calling doesn't appear in the history list after the new document loads. Check the history listing (in your browser's usual spot for this information) before and after clicking Replace Me in Listing 17-10.

### Listing 17-10: Invoking the `location.replace()` Method

```

<HTML>
<HEAD>
<TITLE>location.replace() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
function doReplace() {
 location.replace("lst17-01.htm")
}
</SCRIPT>
</HEAD>
<BODY>
<FORM NAME="myForm">
<INPUT TYPE="button" VALUE="Replace Me" onClick="doReplace()">
</FORM>
</BODY>
</HTML>

```

# History Object

## Properties

### length

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The simple function in Listing 17-11 displays one of two alert messages based on the number of items in the browser's history.

#### Listing 17-11: A Browser History Count

```
<HTML>
<HEAD>
<TITLE>History Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function showCount() {
 var histCount = window.history.length
 if (histCount > 5) {
 alert("My, my, you've been busy. You have visited " + histCount +
" pages so far.")
 } else {
 alert("You have been to " + histCount + " Web pages this session.")
 }
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<INPUT TYPE="button" NAME="activity" VALUE="My Activity" onClick="showCount()">
</FORM>
</BODY>
</HTML>
```

## Methods

### back()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listings 17-12 and 17-13 provide a little workshop in which you can test the behavior of a variety of backward and forward navigation in different browsers. Some features work only in NN4+.

#### Listing 17-12: Navigation Lab Frameset

```
<HTML>
<HEAD>
<TITLE>Back and Forward</TITLE>
</HEAD>
<FRAMESET COLS="45%,55%">
 <FRAME NAME="controller" SRC="lst17-13.htm">
 <FRAME NAME="display" SRC="lst17-01.htm">
</FRAMESET>
</HTML>
```

The top portion of Listing 17-13 contains simple links to other example files from this chapter. A click of any link loads a different document into the right-hand frame to let you build some history inside the frame.

#### Listing 17-13: Navigation Lab Control Panel

```
<HTML>
<HEAD>
<TITLE>Lab Controls</TITLE>
```

*Continued*

## Listing 17-13 (continued)

```

</HEAD>
<BODY>
Load a series of documents into the right frame by clicking some of these
links (make a note of the sequence you click on):<P>
Listing 17-1

Listing 17-5

Listing 17-9

<HR>
<FORM NAME="input">
Click on the various buttons below to see the results in this
frameset:<P>

NN4 Substitute for toolbar buttons -- <TT>window.back()</TT> and
<TT>window.forward()</TT>:<INPUT TYPE="button" VALUE="Back"
onClick="window.back()><INPUT TYPE="button" VALUE="Forward"
onClick="window.forward()><P>

<TT> history.back()</TT> and <TT>history.forward()</TT> for righthand frame:
<INPUT TYPE="button" VALUE="Back" onClick="parent.display.history.back()><INPUT
TYPE="button" VALUE="Forward" onClick="parent.display.history.forward()><P>

<TT>history.back()</TT> for this frame:<INPUT TYPE="button" VALUE="Back"
onClick="history.back()><P>

<TT>history.back()</TT> for parent:<INPUT TYPE="button" VALUE="Back"
onClick="parent.history.back()><P>

</FORM>
</BODY>
</HTML>

```

`go(relativeNumber | "URLorTitleSubstring")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

Fill in either the number or text field of the page in Listing 17-14 and then click the associated button. The script passes the appropriate kind of data to the `go()` method. Be sure to use negative numbers for visiting a page earlier in the history.

### Listing 17-14: Navigating to an Item in History

```
<HTML>
<HEAD>
<TITLE>history.go() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function doGoNum(form) {
 window.history.go(parseInt(form.histNum.value))
}
function doGoTxt(form) {
 window.history.go(form.histWord.value)
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Calling the history.go() method:
<HR>
Enter a number (+/-):<INPUT TYPE="text" NAME="histNum" SIZE=3 VALUE="0">
<INPUT TYPE="button" VALUE="Go to Offset" onClick="doGoNum(this.form)"><P>
Enter a word in a title:<INPUT TYPE="text" NAME="histWord">
<INPUT TYPE="button" VALUE="Go to Match" onClick="doGoTxt(this.form)">
</FORM>
</BODY>
</HTML>
```

## Chapter 18 Examples

The following sections contain examples from Chapter 18, “The Document and Body Objects.”

### Document Object

#### Properties

##### `activeElement`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

#### Example

Use The Evaluator (Chapter 13) with IE4+ to experiment with the `activeElement` property. Type the following statement into the top text box:

```
document.activeElement.value
```

After you press the Enter key, the Results box shows the value of the text box you just typed into (the very same expression you just typed). But if you then click the Evaluate button, you will see the `value` property of that button object appear in the Results box.

`alinkColor`  
`bgColor`  
`fgColor`  
`linkColor`  
`vlinkColor`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

I select some color values at random to plug into three settings of the ugly colors group for Listing 18-1. The smaller window displays a dummy button so that you can see how its display contrasts with color settings. Notice that the script sets the colors of the smaller window by rewriting the entire window's HTML code. After changing colors, the script displays the color values in the original window's textarea. Even though some colors are set with the color constant values, properties come back in the hexadecimal triplet values. You can experiment to your heart's content by changing color values in the listing. Every time you change the values in the script, save the HTML file and reload it in the browser.

### Listing 18-1: Color Sampler

```
<HTML>
<HEAD>
<TITLE>Color Me</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function defaultColors() {
 return "BGCOLOR='#c0c0c0' VLINK='#551a8b' LINK='#0000ff'"
}

function uglyColors() {
 return "BGCOLOR='yellow' VLINK='pink' LINK='lawngreen'"
}

function showColorValues() {
 var result = ""
 result += "bgColor: " + newWindow.document.bgColor + "\n"
 result += "vlinkColor: " + newWindow.document.vlinkColor + "\n"
 result += "linkColor: " + newWindow.document.linkColor + "\n"
 document.forms[0].results.value = result
}

// dynamically writes contents of another window
function drawPage(colorStyle) {
 var thePage = ""
 thePage += "<HTML><HEAD><TITLE>Color Sampler</TITLE></HEAD><BODY "
 if (colorStyle == "default") {
 thePage += defaultColors()
 } else {
 thePage += uglyColors()
 }
 thePage += ">Just so you can see the variety of items and color, <A "
 thePage += "HREF='http://www.nowhere.com'>here's a link, and " +
 " here is another link " +
 "you can use on-line to visit and see how its color differs " +
 "from the standard link."
 thePage += "<FORM>"
}
```

*Continued*

## Listing 18-1 (continued)

```

 thePage += "<INPUT TYPE='button' NAME='sample' VALUE='Just a Button'>"
 thePage += "</FORM></BODY></HTML>"
 newWindow.document.write(thePage)
 newWindow.document.close()
 showColorValues()
}
// the following works properly only in Windows Navigator
function setColors(colorStyle) {
 if (colorStyle == "default") {
 document.backgroundColor = "#c0c0c0"
 } else {
 document.backgroundColor = "yellow"
 }
}
var newWindow = window.open("", "", "height=150,width=300")
</SCRIPT>
</HEAD>

<BODY>
Try the two color schemes on the document in the small window.
<FORM>
<INPUT TYPE="button" NAME="default" VALUE='Default Colors'
 onClick="drawPage('default')">
<INPUT TYPE="button" NAME="weird" VALUE="Ugly Colors"
 onClick="drawPage('ugly')"><P>
<TEXTAREA NAME="results" ROWS=3 COLS=20></TEXTAREA><P><HR>
These buttons change the current document, but not correctly on all platforms<P>
<INPUT TYPE="button" NAME="default" VALUE='Default Colors'
 onClick="setColors('default')">
<INPUT TYPE="button" NAME="weird" VALUE="Ugly Colors"
 onClick="setColors('ugly')"><P>
</FORM>
<SCRIPT LANGUAGE="JavaScript">
drawPage("default")
</SCRIPT>
</BODY>
</HTML>

```

To satisfy the curiosity of those who want to change the color of a loaded document on the fly, the preceding example includes a pair of buttons that set the color properties of the current document. If you're running browsers and versions capable of this power (see Table 18-1), everything will look fine; but in other platforms or earlier versions, you may lose the buttons and other document content behind the color. You can still click and activate these items, but the color obscures them. Unless you know for sure that users of your Web page use only browsers and

clients empowered for background color changes, do not change colors by setting properties of an existing document.

**Note**

If you are using Internet Explorer 3 for the Macintosh, you will experience some difficulties with Listing 18-1. The script in the main document loses its connection with the subwindow; it does not redraw the second window with other colors. You can, however, change the colors in the main document. The significant flicker you may experience is related to the way the Mac version redraws content after changing colors.

## anchors

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

In Listing 18-2, I append an extra script to Listing 17-1 to demonstrate how to extract the number of anchors in the document. The document dynamically writes the number of anchors found in the document. You will not likely ever need to reveal such information to users of your page, and the `document.anchors` property is not one that you will call frequently. The object model defines it automatically as a document property while defining actual anchor objects.

### Listing 18-2: Reading the Number of Anchors

```
<HTML>
<HEAD>
<TITLE>document.anchors Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function goNextAnchor(where) {
 window.location.hash = where
}
</SCRIPT>
</HEAD>

<BODY>

<H1>Top</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="NEXT" onClick="goNextAnchor('sec1')">
</FORM>
```

*Continued*

## Listing 18-2 (continued)

```

<HR>

<H1>Section 1</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="NEXT" onClick="goNextAnchor('sec2')">
</FORM>
<HR>

<H1>Section 2</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="NEXT" onClick="goNextAnchor('sec3')">
</FORM>
<HR>

<H1>Section 3</H1>
<FORM>
<INPUT TYPE="button" NAME="next" VALUE="BACK TO TOP"
onClick="goNextAnchor('start')">
</FORM>
<HR><P>
<SCRIPT LANGUAGE="JavaScript">
document.write("<I>There are " + document.anchors.length +
" anchors defined for this document</I>")
</SCRIPT>
</BODY>
</HTML>

```

## applets

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

The `document.applets` property is defined automatically as the browser builds the object model for a document that contains applet objects. You will rarely access this property, except to determine how many applet objects a document has.

## bgColor

See `alinkColor`.

## body

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to examine properties of the BODY element object. First, to prove that the `document.body` is the same as the element object that comes back from longer references, enter the following statement into the top text box with either IE5 or NN6:

```
document.body == document.getElementsByTagName("BODY")[0]
```

Next, check out the BODY object's property listings later in this chapter and enter the listings into the top text box to review their results. For example:

```
document.body.bgColor
document.body.tagName
```

## charset

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `charset` property. To see the default setting applied to the page, enter the following statement into the top text box:

```
document.charset
```

If you are running IE5+ for Windows 98 and you enter the following statement, the browser will apply a different character set to the page:

```
document.charset = "iso-8859-2"
```

If your version of Windows does not have that character set installed in the system, the browser may ask permission to download and install the character set.

## characterSet

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `characterSet` property in NN6. To see the default setting applied to the page, enter the following statement into the top text box:

```
document.charset
```

## cookie

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Experiment with the last group of statements in Listing 18-3 to create, retrieve, and delete cookies. You can also experiment with The Evaluator by assigning a name/value pair string to `document.cookie`, and then examining the value of the `cookie` property.

## defaultCharset

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `defaultCharset` property. To see the default setting applied to the page, enter the following statement into the top text box:

```
document.defaultCharset
```

## documentElement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Use The Evaluator (Chapter 13) to examine the behavior of the `documentElement` property. In IE5+ or NN6, enter the following statement into the top text field:

```
document.documentElement.tagName
```

The result is HTML, as expected.

## expando

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `document.expando` property in IE4+. Begin by proving that the `document` object can normally accept custom properties. Type the following statement into the top text field:

```
document.spooky = "Boo!"
```

This property is now set and stays that way until the page is either reloaded or unloaded.

Now freeze the `document` object's properties with the following statement:

```
document.expando = false
```

If you try to add a new property, such as the following, you receive an error:

```
document.happy = "tra la"
```

Interestingly, even though `document.expando` is turned off, the first custom property is still accessible and modifiable.

## fgColor

See `aLinkColor`.

`fileCreatedDate`  
`fileModifiedDate`  
`fileSize`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 18-4 dynamically generates several pieces of content relating to the creation and modification dates of the file, as well as its size. More importantly, the listing demonstrates how to turn a value returned by the file date properties into a genuine date object that can be used for date calculations. In the case of Listing 18-4, the calculation is the number of full days between the creation date and the day someone views the file. Notice that the dynamically generated content is added very simply via the `innerText` properties of carefully-located SPAN elements in the body content.

#### Listing 18-4: Viewing File Dates

```
<HTML>
<HEAD>
<TITLE>fileCreatedDate and fileModifiedDate Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

function fillInBlanks() {
 var created = document.fileCreatedDate
 var modified = document.fileModifiedDate
 document.all.created.innerText = created
 document.all.modified.innerText = modified
 var createdDate = new Date(created).getTime()
 var today = new Date().getTime()
 var diff = Math.floor((today - createdDate) / (1000*60*60*24))
 document.all.diff.innerText = diff
 document.all.size.innerText = document.fileSize
}
</SCRIPT>
</HEAD>

<BODY onLoad="fillInBlanks()">
<H1>fileCreatedDate and fileModifiedDate Properties</H1>
<HR>
<P>This file (bytes) was created
on and most
recently modified on .</P>
<P>It has been days since this file was
created.</P>
</BODY>
</HTML>

```

## forms

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The document in Listing 18-5 is set up to display an alert dialog box that simulates navigation to a particular music site, based on the checked status of the “bluish” check box. The user input here is divided into two forms: one form with the check box and the other form with the button that does the navigation. A block of copy fills the space in between. Clicking the bottom button (in the second form) triggers the function that fetches the checked property of the “bluish” checkbox by using the `document.forms[i]` array as part of the address.

**Listing 18-5: Using the document.forms Property**

```

<HTML>
<HEAD>
<TITLE>document.forms example</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function goMusic() {
 if (document.forms[0].bluish.checked) {
 alert("Now going to the Blues music area...")
 } else {
 alert("Now going to Rock music area...")
 }
}
</SCRIPT>
</HEAD>

<BODY>
<FORM NAME="theBlues">
<INPUT TYPE="checkbox" NAME="bluish">Check here if you've got the blues.
</FORM>
<HR>
M

o

r

e

C

o

p

y

<HR>
<FORM NAME="visit">
<INPUT TYPE="button" VALUE="Visit music site" onClick="goMusic()">
</FORM>
</BODY>
</HTML>

```

**frames**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listings 16-7 and 16-8 for examples of using the `frames` property with window objects. The listings works with IE4+ if you swap references to the window with document.

## height width

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓					

### Example

Use The Evaluator (Chapter 13) to examine the `height` and `width` properties of that document. Enter the following statement into the top text box and click the Evaluate button:

```
"height=" + document.height + "; width=" + document.width
```

Resize the window so that you see both vertical and horizontal scrollbars in the browser window and click the Evaluate button again. If either or both numbers get smaller, the values in the Results box are the exact size of the space occupied by the document. But if you expand the window to well beyond where the scrollbars are needed, the values extend to the number of pixels in each dimension of the window's content region.

## images

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓	(✓)		✓	✓	✓

### Example

The `document.images` property is defined automatically as the browser builds the object model for a document that contains image objects. See the discussion about the Image object in Chapter 22 for reference examples.

## implementation

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `document.implementation.hasFeature()` method in NN6. Enter the following statements one at a time into the top text field and examine the results:

```
document.implementation.hasFeature("HTML","1.0")
document.implementation.hasFeature("HTML","2.0")
document.implementation.hasFeature("HTML","3.0")
document.implementation.hasFeature("CSS","2.0")
document.implementation.hasFeature("CSS2","2.0")
```

Feel free to try other values.

## lastModified

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Experiment with the `document.lastModified` property with Listing 18-6. But also be prepared for inaccurate readings if the file is located on some servers or local hard disks.

#### Listing 18-6: `document.lastModified` Property in Another Format

```
<HTML>
<HEAD>
<TITLE>Time Stamper</TITLE>
</HEAD>
<BODY>
```

```

<CENTER> <H1>GiantCo Home Page</H1></CENTER>
<SCRIPT LANGUAGE="JavaScript">
update = new Date(document.lastModified)
theMonth = update.getMonth() + 1
theDate = update.getDate()
theYear = update.getFullYear()
document.writeln("<I>Last updated:" + theMonth + "/" + theDate + "/" + theYear +
"</I>")
</SCRIPT>
<HR>
</BODY>
</HTML>

```

As noted at great length in Chapter 36's discussion about the `Date` object, you should be aware that date formats vary greatly from country to country. Some of these formats use a different order for date elements. When you hard-code a date format, it may take a form that is unfamiliar to other users of your page.

## Layers

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

Listing 18-7 demonstrates only for NN4 how to use the `document.layers` property to crawl through the entire set of nested layers in a document. Using reflexive calls to the `crawlLayers()` function, the script builds an indented list of layers in the same hierarchy as the objects themselves and displays the results in an alert dialog box. After you load this document (the script is triggered by the `onLoad` event handler), compare the alert dialog box contents against the structure of `<LAYER>` tags in the document.

#### Listing 18-7: A Navigator 4 Layer Crawler

```

<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript1.2">
var output = ""

```

*Continued*

**Listing 18-7 (continued)**

```

function crawlLayers(layerArray, indent) {
 for (var i = 0; i < layerArray.length; i++) {
 output += indent + layerArray[i].name + "\n"
 if (layerArray[i].document.layers.length) {
 var newLayerArray = layerArray[i].document.layers
 crawlLayers(newLayerArray, indent + " ")
 }
 }
 return output
}
function revealLayers() {
 alert(crawlLayers(document.layers, ""))
}
</SCRIPT>
</HEAD>
<BODY onLoad="revealLayers()">
<LAYER NAME="Europe">
 <LAYER NAME="Germany"></LAYER>
 <LAYER NAME="Netherlands">
 <LAYER NAME="Amsterdam"></LAYER>
 <LAYER NAME="Rotterdam"></LAYER>
 </LAYER>
 <LAYER NAME="France"></LAYER>
</LAYER>
<LAYER NAME="Africa">
 <LAYER NAME="South Africa"></LAYER>
 <LAYER NAME="Ivory Coast"></LAYER>
</LAYER>
</BODY>
</HTML>

```

## linkColor

See `alinkColor`.

## links

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The `document.links` property is defined automatically as the browser builds the object model for a document that contains link objects. You rarely access this property, except to determine the number of link objects in the document.

## Location URL

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	(✓)	✓	✓	✓	(✓)	(✓)	✓	✓	✓

## Example

HTML documents in Listing 18-8 through 18-10 create a test lab that enables you to experiment with viewing the `document.URL` property for different windows and frames in a multiframe environment. Results are displayed in a table, with an additional listing of the `document.title` property to help you identify documents being referred to. The same security restrictions that apply to retrieving `window.location` object properties also apply to retrieving the `document.URL` property from another window or frame.

### Listing 18-8: Frameset for document.URL Property Reader

```
<HTML>
<HEAD>
<TITLE>document.URL Reader</TITLE>
</HEAD>
<FRAMESET ROWS="60%,40%">
 <FRAME NAME="Frame1" SRC="1st18-10.htm">
 <FRAME NAME="Frame2" SRC="1st18-09.htm">
</FRAMESET>
</HTML>
```

### Listing 18-9 document.URL Property Reader

```

<HTML>
<HEAD>
<TITLE>URL Property Reader</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
function fillTopFrame() {
 newURL=prompt("Enter the URL of a document to show in the top frame:", "")
 if (newURL != null && newURL != "") {
 top.frames[0].location = newURL
 }
}

function showLoc(form,item) {
 var windName = item.value
 var theRef = windName + ".document"
 form.dLoc.value = unescape(eval(theRef + ".URL"))
 form.dTitle.value = unescape(eval(theRef + ".title"))
}
</SCRIPT>
</HEAD>

<BODY>
Click the "Open URL" button to enter the location of an HTML document to display
in the upper frame of this window.
<FORM>
<INPUT TYPE="button" NAME="opener" VALUE="Open URL..." onClick="fillTopFrame()">
</FORM>
<HR>
<FORM>
Select a window or frame to view each document property values.<P>
<INPUT TYPE="radio" NAME="whichFrame" VALUE="parent"
onClick="showLoc(this.form,this)">Parent window
<INPUT TYPE="radio" NAME="whichFrame" VALUE="top.frames[0]"
onClick="showLoc(this.form,this)">Upper frame
<INPUT TYPE="radio" NAME="whichFrame" VALUE="top.frames[1]"
onClick="showLoc(this.form,this)">This frame<P>
<TABLE BORDER=2>
<TR><TD ALIGN=RIGHT>document.URL:</TD>
<TD><TEXTAREA NAME="dLoc" ROWS=3 COLS=30 WRAP="soft"></TEXTAREA></TD></TR>

<TR><TD ALIGN=RIGHT>document.title:</TD>
<TD><TEXTAREA NAME="dTitle" ROWS=3 COLS=30 WRAP="soft"></TEXTAREA></TD></TR>
</TABLE>
</FORM>
</BODY>
</HTML>

```

**Listing 18-10: Placeholder for Listing 18-8**

```

<HTML>
<HEAD>
<TITLE>Opening Placeholder</TITLE>
</HEAD>
<BODY>
Initial place holder. Experiment with other URLs for this frame (see below).
</BODY>
</HTML>

```

**parentWindow**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

To prove the `parentWindow` property points to the document's window, you can enter the following statement into the top text field of The Evaluator (Chapter 13):

```
document.parentWindow == self
```

This expression evaluates to `true` only if both references are of the same object.

**protocol**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

If you use The Evaluator (Chapter 13) to test the `document.protocol` property, you will find that it displays `File Protocol` in the results because you are accessing the listing from a local hard disk or CD-ROM.

## referrer

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

This demonstration requires two documents (and for IE, you'll also need to access the documents from a Web server). The first document, in Listing 18-11, simply contains one line of text as a link to the second document. In the second document (Listing 18-12), a script verifies the document from which the user came via a link. If the script knows about that link, it displays a message relevant to the experience the user had at the first document. Also try opening Listing 18-12 in a new browser window from the Open File command in the File menu to see how the script won't recognize the referrer.

**Listing 18-11: A Source Document**

```
<HTML>
<HEAD>
<TITLE>document.referrer Property 1</TITLE>
</HEAD>

<BODY>
<H1>Visit my sister document
</BODY>
</HTML>
```

**Listing 18-12: Checking document.referrer**

```
<HTML>
<HEAD>
<TITLE>document.referrer Property 2</TITLE>
</HEAD>

<BODY><H1>
<SCRIPT LANGUAGE="JavaScript">
if(document.referrer.length > 0 && document.referrer.indexOf("18-11.htm") != -1){
```

```

 document.write("How is my brother document?")
 } else {
 document.write("Hello, and thank you for stopping by.")
 }
</SCRIPT>
</H1></BODY>
</HTML>

```

## scripts

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

You can experiment with the `document.scripts` array in The Evaluator (Chapter 13). For example, you can see that only one `SCRIPT` element object is in The Evaluator page if you enter the following statement into the top text field:

```
document.scripts.length
```

If you want to view all of the properties of that lone `SCRIPT` element object, enter the following statement into the bottom text field:

```
document.scripts[0]
```

Among the properties are both `innerText` and `text`. If you assign an empty string to either property, the scripts are wiped out from the object model, but not from the browser. The scripts disappear because after the scripts loaded, they were cached outside of the object model. Therefore, if you enter the following statement into the top field:

```
document.scripts[0].text = ""
```

the script contents are gone from the object model, yet subsequent clicks of the Evaluate and List Properties buttons (which invoke functions of the `SCRIPT` element object) still work.

## selection

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listings 15-30 and 15-39 in Chapter 15 to see the `document.selection` property in action for script-controlled copying and pasting (IE/Windows only).

## URL

See `location`.

## vlinkColor

See `alinkColor`.

## width

See `height`.

## Methods

### `captureEvents(eventTypeList)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

See the example for the NN4 `window.captureEvents()` method in Chapter 16 (Listing 16-21) to see how to capture events on their way to other objects. In that example, you can substitute the `document` reference for the `window` reference to see how the document version of the method works just like the window version. If you understand the mechanism for windows, you understand it for documents. The same is true for the other NN4 event methods.

## close()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Before you experiment with the `document.close()` method, be sure you understand the `document.write()` method described later in this chapter. After that, make a separate set of the three documents for that method's example (Listings 18-16 through 18-18 in a different directory or folder). In the `takePulse()` function listing, comment out the `document.close()` statement, as shown here:

```
msg += "<P>Make it a great day!</BODY></HTML>"
parent.frames[1].document.write(msg)
//parent.frames[1].document.close()
```

Now try the pages on your browser. You see that each click of the upper button appends text to the bottom frame, without first removing the previous text. The reason is that the previous layout stream was never closed. The document thinks that you're still writing to it. Also, without properly closing the stream, the last line of text may not appear in the most recently written batch.

## createAttribute("attributeName")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Unfortunately, the `setAttributeNode()` method in NN6 does not yet work with attributes generated by the `createAttribute()` method. This will be fixed eventually, and you can experiment adding attributes to sample elements in The Evaluator. In the meantime, you can still create an attribute and inspect its properties. Enter the following text into the top text box:

```
a = document.createAttribute("author")
```

Now enter `a` into the bottom text box to inspect the properties of an `Attr` object.

`createElement("tagName")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

**Example**

Chapter 15 contains numerous examples of the `document.createElement()` method in concert with methods that add or replace content to a document. See Listings 15-10, 15-21, 15-22, 15-28, 15-29, and 15-31.

`createEventObject([eventObject])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility									✓

**Example**

See the discussion of the `fireEvent()` method in Chapter 15 for an example of the sequence to follow when creating an event to fire on an element.

`createStyleSheet(["URL"[ , index]])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

**Example**

Listing 18-13 demonstrates adding an internal and external style sheet to a document. For the internal addition, the `addStyle1()` function invokes `document.createStyleSheet()` and adds a rule governing the P elements of the page (not available for IE5/Mac). In the `addStyle2()` function, an external file is loaded. That file contains the following two style rules:

```
H2 {font-size:20pt; color:blue}
P {color:blue}
```

Notice that by specifying a position of zero for the imported style sheet, the addition of the internal style sheet always comes afterward in `styleSheet` object sequence. Thus, except when you deploy only the external style sheet, the red text color of the `P` elements override the blue color of the external style sheet. If you remove the second parameter of the `createStyleSheet()` method in `addStyle2()`, the external style sheet is appended to the end of the list. If it is the last style sheet to be added, the blue color prevails. Repeatedly clicking the buttons in this example continues to add the style sheets to the document.

### Listing 18-13: Using `document.createStyleSheet()`

```
<HTML>
<HEAD>
<TITLE>document.createStyleSheet() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function addStyle1() {
 var newStyle = document.createStyleSheet()
 newStyle.addRule("P", "font-size:16pt; color:red")
}

function addStyle2() {
 var newStyle = document.createStyleSheet("1st18-13.css",0)
}
</SCRIPT>
</HEAD>

<BODY>
<H1>document.createStyleSheet() Method</H1>
<HR>
<FORM>
<INPUT TYPE="button" VALUE="Add Internal" onClick="addStyle1()">
<INPUT TYPE="button" VALUE="Add External" onClick="addStyle2()">
</FORM>
<H2>Section 1</H2>
<P>Lorem ipsum dolor sit amet, consectetur adipiscing elit,
sed do eiusmod tempor incididunt ut labore et dolore magna aliqua.

</BODY>
</HTML>
```

`createTextNode("text")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

**Example**

While Chapter 14 and 15 (Listing 15-21, for instance) provide numerous examples of the `createTextNode()` method at work, using The Evaluator (Chapter 13) is instructive to see just what the method generates in IE5+ and NN6. You can use one of the built-in global variables of The Evaluator to hold a reference to a newly generated text node by entering the following statement into the top text field:

```
a = document.createTextNode("Hello")
```

The Results box shows that an object was created. Now, look at the properties of the object by typing `a` into the bottom text field. The precise listings of properties varies between IE5+ and NN6, but the W3C DOM properties that they share in common indicate that the object is a node type 3 with a node name of `#text`. No parents, children, or siblings exist yet because the object created here is not part of the document hierarchy tree until it is explicitly added to the document.

To see how insertion works, enter the following statement into the top text field to append the text node to the `myP` paragraph:

```
document.getElementById("myP").appendChild(a)
```

The word “Hello” appears at the end of the simple paragraph lower on the page. Now you can modify the text of that node either via the reference from the point of view of the containing `P` element or via the global variable reference for the newly created node:

```
document.getElementById("myP").lastChild.nodeValue = "Howdy"
```

or

```
a.nodeValue = "Howdy"
```

## elementFromPoint(x, y)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 18-14 is a document that contains many different types of elements, each of which has an ID attribute assigned to it. The `onMouseOver` event handler for the document object invokes a function that finds out which element the cursor is over when the event fires. Notice that the event coordinates are `event.clientX` and `event.clientY`, which use the same coordinate plane as the page for their point of reference. As you roll the mouse over every element, its ID appears on the page. Some elements, such as `BR` and `TR`, occupy no space in the document, so you cannot get their IDs to appear. On a typical browser screen size, a positioned element rests atop one of the paragraph elements so that you can see how the `elementFromPoint()` method handles overlapping elements. If you scroll the page, the coordinates for the event and the page's elements stay in sync.

### Listing 18-14: Using the `elementFromPoint()` Method

```
<HTML>
<HEAD>
<TITLE>document.elementFromPoint() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function showElemUnderneath() {
 var elem = document.elementFromPoint(event.clientX, event.clientY)
 document.all.mySpan.innerText = elem.id
}
document.onmouseover = showElemUnderneath
</SCRIPT>
</HEAD>

<BODY ID="myBody">
<H1 ID="header">document.elementFromPoint() Method</H1>
<HR ID="myHR">
<P ID="instructions">Roll the mouse around the page. The coordinates
of the mouse pointer are currently atop an element<BR ID="myBR">whose ID
is:"".</P>
<FORM ID="myForm">
<INPUT ID="myButton" TYPE="button" VALUE="Sample Button" onClick="">
</FORM>
```

*Continued*

**Listing 18-14 (continued)**

```

<TABLE BORDER=1 ID="myTable">
<TR ID="tr1">
 <TD ID="td_A1">Cell A1</TD>
 <TD ID="td_B1">Cell B1</TD>

Ut enim adminim veniam, quis nostrud exercitation ullamco laboris
nisi ut aliquip ex ea commodo consequat.</P>
<H2 ID="sec2">Section 2</H2>
<P ID="p2">Duis aute irure dolor in reprehenderit involuptate velit esse
cillum dolore eu fugiat nulla pariatur. Excepteur sint occaecat
cupidatat non proident, sunt in culpa qui officia deseruntmollit
anim id est laborum.</P>
<DIV ID="myDIV" STYLE="position:absolute; top:340; left:300; background-
color:yellow">
Here is a positioned element.</DIV>
</BODY>
</HTML>

```

`execCommand("commandName" [, UIFlag] [, param])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

You can find many examples of the `execCommand()` method for the `TextRange` object in Chapter 19. But you can try out the document-specific commands in The Evaluator (Chapter 13) if you like. Try each of the following statements in the top text box and click the Evaluate button:

```
document.execCommand("Refresh")
document.execCommand("SelectAll")
document.execCommand("Unselect")
```

All methods return `true` in the Results box.

Because any way you can evaluate a statement in The Evaluator forces a body selection to become deselected before the evaluation takes place, you can't experiment this way with the selection-oriented commands.

## getElementById("elementID")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

You can find many examples of this method in use throughout this book, but you can take a closer look at how it works by experimenting in The Evaluator (Chapter 13). A number of elements in The Evaluator have IDs assigned to them, so that you can use the method to inspect the objects and their properties. Enter the following statements into both the top and bottom text fields of The Evaluator. Results from the top field are references to the objects; results from the bottom field are lists of properties for the particular object.

```
document.getElementById("myP")
document.getElementById("myEM")
document.getElementById("myTitle")
document.getElementById("myScript")
```

As you see in the Results field, NN6 is more explicit about the type of HTML element object being referenced in the top text field than IE5. But both browsers are pointing to the same objects just the same.

## getElementsByName("elementName")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

## Example

Use The Evaluator to test out the `getElementsByName()` method. All form elements in the upper part of the page have names associated with them. Enter the following statements into the top text field and observe the results:

```
document.getElementsByName("output")
document.getElementsByName("speed").length
document.getElementsByName("speed")[0].value
```

You can also explore all of the properties of the text field by typing the following expression into the bottom field:

```
document.getElementsByName("speed")[0]
```

## getSelection()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓					

## Example

The document in Listing 18-15 provides a cross-browser (but not IE5/Mac) solution to capturing text that a user selects in the page. Selected text is displayed in the textarea. The script uses browser detection and branching to accommodate the diverse ways of recognizing the event and reading the selected text.

### Listing 18-15: Capturing a Text Selection

```
<HTML>
<HEAD>
<TITLE>Getting Selected Text</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var isNav4 = (navigator.appName == "Netscape" &&
parseInt(navigator.appVersion) == 4)
var isNav4Min = (navigator.appName == "Netscape" &&
parseInt(navigator.appVersion) >= 4)
var isIE4Min = (navigator.appName.indexOf("Microsoft") != -1 &&
parseInt(navigator.appVersion) >= 4)
function showSelection() {
if (isNav4Min) {
document.forms[0].selectedText.value = document.getSelection()
} else if (isIE4Min) {
```

```

 if (document.selection) {
 document.forms[0].selectedText.value =
 document.selection.createRange().text
 event.cancelBubble = true
 }
 }
}
if (isNav4) {
 document.captureEvents(Event.MOUSEUP)
}
document.onmouseup = showSelection
</SCRIPT>
</HEAD>

<BODY>
<H1>Getting Selected Text</H1>
<HR>
<P>Select some text and see how JavaScript can capture the selection:</P>
<H2>ARTICLE I</H2>
<P>
Congress shall make no law respecting an establishment of religion, or
prohibiting the
free exercise thereof; or abridging the freedom of speech, or of the press; or
the right of the people peaceably to assemble, and to petition the government
for a redress of grievances.
</P>
</HR>
<FORM>
<TEXTAREA NAME="selectedText" ROWS=3 COLS=40 WRAP="virtual"></TEXTAREA>
</FORM>
</BODY>
</HTML>

```

`open(["mimeType"] [, replace])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

You can see an example of where the `document.open()` method fits in the scheme of dynamically creating content for another frame in the discussion of the `document.write()` method, later in this chapter.

```

queryCommandEnabled("commandName")
queryCommandIndterm("commandName")
queryCommandCommandState("commandName")
queryCommandSupported("commandName")
queryCommandText("commandName")
queryCommandValue("commandName")

```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See the examples for these methods covered under the `TextRange` object in Chapter 19.

```
recalc([allFlag])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

You can see an example of `recalc()` in Listing 15-32 for the `setExpression()` method. In that example, the dependencies are between the current time and properties of standard element objects.

```

write("string1" [, "string2" ... [, "stringn"]])
writeln("string1" [, "string2" ... [, "stringn"]])

```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The example in Listings 18-16 through 18-18 demonstrates several important points about using the `document.write()` or `document.writeln()` methods for writing to another frame. First is the fact that you can write any HTML code to a frame, and the browser accepts it as if the source code came from an HTML file somewhere. In the example, I assemble a complete HTML document, including basic HTML tags for completeness.

### Listing 18-16: Frameset for `document.write()` Example

```
<HTML>
<HEAD>
<TITLE>Writin' to the doc</TITLE>
</HEAD>
<FRAMESET ROWS="50%,50%">
 <FRAME NAME="Frame1" SRC="lst18-17.htm">
 <FRAME NAME="Frame2" SRC="lst18-18.htm">
</FRAMESET>
</HTML>
```

### Listing 18-17: `document.write()` Example

```
<HTML>
<HEAD>
<TITLE>Document Write Controller</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function takePulse(form) {
 var msg = "<HTML><HEAD><TITLE>On The Fly with " + form.yourName.value +
 "</TITLE></HEAD>"
 msg += "<BODY BGCOLOR='salmon'><H1>Good Day " + form.yourName.value +
 "!</H1><HR>"
 for (var i = 0; i < form.how.length; i++) {
 if (form.how[i].checked) {
 msg += form.how[i].value
 break
 }
 }
 msg += "<P>Make it a great day!</BODY></HTML>"
 parent.Frame2.document.write(msg)
 parent.Frame2.document.close()
}
```

*Continued*

**Listing 18-17 (continued)**

```

function getTitle() {
 alert("Lower frame document.title is now:" + parent.Frame2.document.title)
}
</SCRIPT>
</HEAD>

<BODY>
Fill in a name, and select how that person feels today. Then click "Write To
Below"
to see the results in the bottom frame.
<FORM>
Enter your first name:<INPUT TYPE="text" NAME="yourName" VALUE="Dave"><P>
How are you today? <INPUT TYPE="radio" NAME="how"
VALUE="I hope that feeling continues forever." CHECKED>Swell
<INPUT TYPE="radio" NAME="how" VALUE="You may be on your way to feeling Swell">
Pretty Good
<INPUT TYPE="radio" NAME="how" VALUE="Things can only get better from here.">
So-So<P>
<INPUT TYPE="button" NAME="enter" VALUE="Write To Below"
onClick="takePulse(this.form)">
<HR>
<INPUT TYPE="button" NAME="peek" VALUE="Check Lower Frame Title"
onClick="getTitle()">
</BODY>
</HTML>

```

---

**Listing 18-18: Placeholder for Listing 18-16**

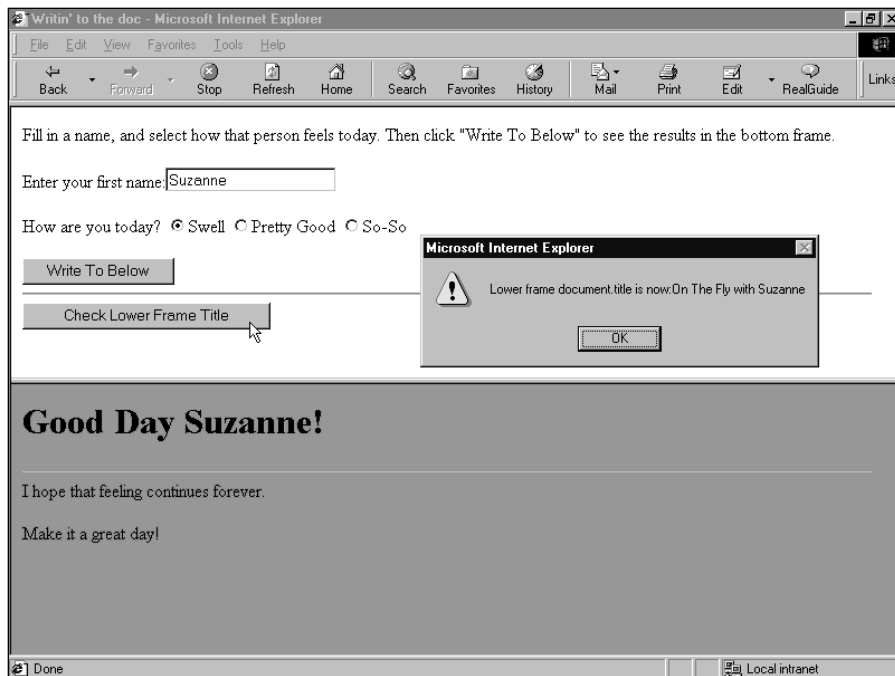

```

<HTML>
<HEAD>
<TITLE>Placeholder</TITLE>
<BODY>
</BODY>
</HTML>

```

---

Figure 18-2 shows an example of the frame written by the script.

**Figure 18-2:** Clicking the Write To Below button in the upper frame causes a script to assemble and write HTML for the bottom frame.

A second point to note is that this example customizes the content of the document based on user input. This customization makes the experience of working with your Web page feel far more interactive to the user — yet you're doing it without any CGI programs running on the server.

The third point I want to bring home is that the document created in the separate frame by the `document.write()` method is a genuine `document` object. In this example, for instance, the `<TITLE>` tag of the written document changes if you redraw the lower frame after changing the entry of the name field in the upper frame. If you click the lower button after updating the bottom frame, you see that the `document.title` property has, indeed, changed to reflect the `<TITLE>` tag written to the browser in the course of displaying the frame's page (except in NN4/Mac, which exhibits a bug for this property in a dynamically written document). The fact that you can artificially create full-fledged, JavaScript `document` objects on the fly represents one of the most important powers of serverless CGI scripting (for information delivery to the user) with JavaScript. You have much to take advantage of here if your imagination is up to the task.

Notice that except for NN2, you can easily modify Listing 18-17 to write the results to the same frame as the document containing the field and buttons. Instead of specifying the lower frame

```
parent.frames[1].document.open()
parent.frames[1].document.write(msg)
parent.frames[1].document.close()
```

the code simply can use

```
document.open()
document.write(msg)
document.close()
```

This code would replace the form document with the results and not require any frames in the first place. Because the code assembles all of the content for the new document into one variable value, that data survive the one `document.write()` method.

The frameset document (Listing 18-18) creates a blank frame by loading a blank document (Listing 18-18). An alternative I highly recommend is to have the framesetting document fill the frame with a blank document of its own creation. See “Blank Frames” in Chapter 16 for further details about this technique for NN3+ and IE3+.

## Event Handlers

### onStop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 18-19 provides a simple example of an intentional infinitely looping script. In case you load this page into a browser other than IE5, you can click the Halt Counter button to stop the looping. The Halt Counter button as well as the `onStop` event handler invoke the same function.

**Listing 18-19: Scripting the Browser Stop Button**

```
<HTML>
<HEAD>
<TITLE>onStop Event Handler</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var counter = 0
var timerID
function startCounter() {
 document.forms[0].display.value = ++counter
 //clearTimeout(timerID)
 timerID = setTimeout("startCounter()", 10)
}
function haltCounter() {
 clearTimeout(timerID)
 counter = 0
}
document.onstop = haltCounter
</SCRIPT>
</HEAD>

<BODY>
<H1>onStop Event Handler</H1>
<HR>
<P>Click the browser's Stop button (in IE) to stop the script counter.</P>
<FORM>
<P><INPUT TYPE="text" NAME="display"></P>
<INPUT TYPE="button" VALUE="Start Counter" onClick="startCounter()">
<INPUT TYPE="button" VALUE="Halt Counter" onClick="haltCounter()">
</FORM>
</BODY>
</HTML>
```

---

# BODY Element Object

## Properties

aLink  
bgColor  
link  
text  
vLink

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

You can modify Listing 18-1 for use with IE4+ and NN6+ only by using the new property names instead. Replace all references to the `document` properties with their `document.body` equivalents. For example, the function would be reworked as the following (changes in boldface):

```
function showColorValues() {
 var result = ""
 result += "bgColor: " + newWindow.document.body.bgColor + "\n"
 result += "vLink: " + newWindow.document.body.vLink + "\n"
 result += "link: " + newWindow.document.body.link + "\n"
 document.forms[0].results.value = result
}
```

## background

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

If you have a background image file named `images/logoBG.gif`, a script can set the background via the following statement:

```
document.body.background = "images/logoBG.gif"
```

To clear the background image:

```
document.body.background = ""
```

If a background color has been previously set, the color becomes visible after the image disappears.

## bgColor

See `aLink`.

## bgProperties

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Both of the following statements change the default behavior of background image scrolling in IE4+:

```
document.body.bgProperties = "fixed"
```

or

```
document.body.style.backgroundAttachment = "fixed"
```

The added benefit of using the style sheet version is that it also works in NN6.

bottomMargin  
leftMargin  
rightMargin  
topMargin

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Both of the following statements change the default left margin in IE4+:

```
document.body.leftMargin = 30
```

or

```
document.body.style.marginLeft = 30
```

## leftMargin

See bottomMargin.

## link

See aLink.

## noWrap

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

To change the word wrapping behavior from the default, the statement is:

```
document.body.noWrap = true
```

## rightMargin

See `bottomMargin`.

## scroll

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

To change the scrollbar appearance from the default, the statement is:

```
document.body.scroll = "no"
```

## scrollLeft scrollTop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 18-20 is the IE4+ version of the NN example for `pageXOffset` and `pageYOffset` properties (Listing 16-13). Everything about these two examples is the same except for the syntax that retrieves the values indicating how much the document is scrolled in a window.

### Listing 18-20: Viewing the scrollLeft and scrollTop Properties

```
<HTML>
<HEAD>
<TITLE>Master of all Windows</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function leftFrame() {
 var output = "<HTML><BODY><H3>Body Scroll Values</H3><HR>\n"
```

*Continued*

## Listing 18-20 (continued)

```

 output += "<FORM>body.scrollLeft:<INPUT TYPE='text' NAME='xOffset'
SIZE=4>
\n"
 output += "body.scrollTop:<INPUT TYPE='text' NAME='yOffset' SIZE=4>
\n"
 output += "</FORM></BODY></HTML>"
 return output
}

function rightFrame() {
 var output = "<HTML><HEAD><SCRIPT LANGUAGE='JavaScript'>\n"
 output += "function showOffsets() {\n"
 output += "parent.readout.document.forms[0].xOffset.value = " +
 "document.body.scrollLeft\n"
 output += "parent.readout.document.forms[0].yOffset.value = " +
 "document.body.scrollTop}\n"
 output += "document.onclick = showOffsets\n"
 output += "</SCRIPT></HEAD><BODY><H3>Content Page</H3>\n"
 output += "Scroll this frame and click on a table border to view " +
 "page offset values.
<HR>\n"
 output += "<TABLE BORDER=5 WIDTH=800>"
 var oneRow = "<TD>Cell 1</TD><TD>Cell 2</TD><TD>Cell 3</TD><TD>Cell 4</TD>" +
 "<TD>Cell 5</TD>"
 for (var i = 1; i <= 30; i++) {
 output += "<TR><TD>Row " + i + "</TD>" + oneRow + "</TR>"
 }
 output += "</TABLE></BODY></HTML>"
 return output
}
</SCRIPT>
</HEAD>
<FRAMESET COLS="30%,70%">
 <FRAME NAME="readout" SRC="javascript:parent.leftFrame()">
 <FRAME NAME="display" SRC="javascript:parent.rightFrame()">
</FRAMESET>
</HTML>

```

## text

See aLink.

## topMargin

See bottomMargin.

## vLink

See aLink.

## Methods

### createTextRange()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 19-8 for an example of the `createTextRange()` method in action.

### doScroll(["scrollAction"])

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `doScroll()` method in IE5+. Size the browser window so that at least the vertical scrollbar is active (meaning it has a thumb region). Enter the following statement into the top text field and press Enter a few times to simulate clicking the PgDn key:

```
document.body.doScroll()
```

Return to the top of the page and now do the same for scrolling by the increment of the scrollbar down arrow:

```
document.body.doScroll("down")
```

You can also experiment with upward scrolling. Enter the desired statement in the top text field and leave the text cursor in the field. Manually scroll to the bottom of the page and then press Enter to activate the command.

## Event Handlers

### onAfterPrint onBeforePrint

See the `onAfterPrint` event handler for the window object, Chapter 16.

### onScroll

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 18-21 is a highly artificial demonstration of what can be a useful tool for some page designs. Consider a document that occupies a window or frame, but one that you don't want scrolled, even by accident with one of the newer mouse wheels that are popular with Wintel PCs. If scrolling of the content would destroy the appearance or value of the content, then you want to make sure that the page always zips back to the top. The `onScroll` event handler in Listing 18-21 does just that. Notice that the event handler is set as a property of the `document.body` object after the page has loaded. While the event handler can also be set as an attribute of the `<BODY>` tag, to assign it as a property requires the page to load first. Until then, the `document.body` object does not yet officially exist in the object model for this page.

#### Listing 18-21: Forcing Scrolling to Stay at the Page Top

```
<HTML>
<HEAD>
<TITLE>onScroll Event Handler</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function zipBack() {
 window.scroll(0,0)
}
function init() {
 document.body.onscroll = zipBack
}
</SCRIPT>
</HEAD>

<BODY onLoad="init()">
```

```

<H1>onScroll Event Handler</H1>
<HR>
This page always zips back to the top if you try to scroll it.
<P>
<IFRAME FRAMEBORDER=0 SCROLLING="no" HEIGHT=1000 SRC="bofright.htm"></IFRAME>
</P>
</BODY>
</HTML>

```

## Chapter 19 Examples

The following sections contain examples from Chapter 19, “Body Text Objects.”

## FONT Element Object

### Properties

color

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Listing 19-1 contains a page that demonstrates changes to the three FONT element object properties: color, face, and size. Along the way, you can see an economical use of the `setAttribute()` method to do the work for all of the property changes. This page loads successfully in all browsers, but the SELECT lists make changes to the text only in IE4+ and NN6+.

A P element contains a nested FONT element that encompasses three words whose appearance is controlled by three select lists. Each list controls one of the three FONT object properties, and their NAME attributes are strategically assigned the names of the properties (as you see in a moment). VALUE attributes for OPTION elements contain strings that are to be assigned to the various properties. Each SELECT element invokes the same `setFontAttr()` function, passing a reference to itself so that the function can inspect details of the element.

The first task of the `setFontAttr()` function is to make sure that only browsers capable of treating the `FONT` element as an object get to the meat of the function. The test for the existence of `document.all` and the `myFONT` element blocks all older browsers from changing the font characteristics. As the page loads, the `document.all` property is set for NN6 by using a variation of the normalization technique described in Chapter 14.

For suitably equipped browsers, the function next extracts the string from the `value` property of the `SELECT` object that was passed to the function. If a selection is made (meaning other than the first, empty one), then the single nested statement uses the `setAttribute()` method to assign the value to the attribute whose name matches the name of the `SELECT` element.

**Note**

An odd bug in IE5/Mac doesn't let the rendered color change when changing the `color` property. But the setting is valid, as proven by selecting any of the other two property choices.

### Listing 19-1: Controlling FONT Object Properties

```
<HTML>
<HEAD>
<TITLE>FONT Object Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// document.all normalization trick for NN6
if (navigator.appName == "Netscape" && parseInt(navigator.appVersion) >= 5) {
 document.all = document.getElementsByTagName("*")
}

// one function does all!
function setFontAttr(select) {
 if (document.all && document.all.myFONT) {
 var choice = select.options[select.selectedIndex].value
 if (choice) {
 document.all.myFONT.setAttribute(select.name, choice)
 }
 }
}
</SCRIPT>
</HEAD>

<BODY>
<H1>Font Object Properties</H1>

<P>This may look like a simple sentence, but
THESE THREE WORDS
are contained by a FONT element.</P>
```

```

<FORM>
Select a text color:
<SELECT NAME="color" onChange="setFontAttr(this)">
 <OPTION></OPTION>
 <OPTION VALUE="red">Red</OPTION>
 <OPTION VALUE="green">Green</OPTION>
 <OPTION VALUE="blue">Blue</OPTION>
 <OPTION VALUE="#FA8072">Some Hex Triplet Value</OPTION>
</SELECT>

Select a font face:
<SELECT NAME="face" onChange="setFontAttr(this)">
 <OPTION></OPTION>
 <OPTION VALUE="Helvetica">Helvetica</OPTION>
 <OPTION VALUE="Times">Times</OPTION>
 <OPTION VALUE="Comic Sans MS, sans-serif">Comic Sans MS, sans-serif</OPTION>
 <OPTION VALUE="Courier, monospace">Courier, monospace</OPTION>
 <OPTION VALUE="Zapf Dingbats, serif">Zapf Dingbats, serif</OPTION>
</SELECT>

Select a font size:
<SELECT NAME="size" onChange="setFontAttr(this)">
 <OPTION></OPTION>
 <OPTION VALUE="3">3 (Default)</OPTION>
 <OPTION VALUE="+1">Increase Default by 1</OPTION>
 <OPTION VALUE="-1">Decrease Default by 1</OPTION>
 <OPTION VALUE="1">Smallest</OPTION>
 <OPTION VALUE="7">Biggest</OPTION>
</SELECT>
</BODY>
</HTML>

```

## face

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

See Listing 19-1 for an example of values that can be used to set the `face` property of a `FONT` element object. While you will notice visible changes to most choices on the page, the font face selections may not change from one choice to another, which all depends on the fonts that are installed on your PC.

## size

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

**Example**

See Listing 19-1 for an example of values that can be used to set the `size` property of a `FONT` element object. Notice that incrementing or decrementing the `size` property is applied only to the size assigned to the `SIZE` attribute of the element (or the default, if none is specified) and not the current setting adjusted by script.

## HR Element Object

### Properties

## align

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

**Example**

Listing 19-2 contains a page that demonstrates the changes to the five HR element object properties: `align`, `color`, `noShade`, `size`, and `width`. Along the way, you can see an economical use of the `setAttribute()` method to do the work for all of the property changes. This page loads successfully in all browsers, but the `SELECT` lists make changes to the text only in IE4+ and NN6+ (because they treat the element as an object).

An HR element (whose ID is `myHR`) is displayed with the browser default settings (100% width, centered, and its “magic” color). Each list controls one of the five HR object properties, and their `NAME` attributes are strategically assigned the names of the properties (as you see in a moment). `VALUE` attributes for `OPTION` elements contain strings that are to be assigned to the various properties. Each `SELECT` element invokes the same `setHRAttr()` function, passing a reference to itself so that the function can inspect details of the element.

The first task of the `setHRAttr()` function is to make sure that only browsers capable of treating the HR element as an object get to the meat of the function. As the page loads, the `document.all` property is set for NN6 using a normalization technique described in Chapter 14.

For suitably equipped browsers, the function next reads the string from the `value` property of the SELECT object that is passed to the function. If a selection is made (that is, other than the first, empty one), then the single, nested statement uses the `setAttribute()` method to assign the value to the attribute whose name matches the name of the SELECT element.

### Listing 19-2: Controlling HR Object Properties

```
<HTML>
<HEAD>
<TITLE>HR Object Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// document.all normalization trick for NN6
if (navigator.appName == "Netscape" && parseInt(navigator.appVersion) >= 5) {
 document.all = document.getElementsByTagName("*")
}

// one function does all!
function setHRAttr(select) {
 if (document.all && document.all.myHR) {
 var choice = select.options[select.selectedIndex].value
 if (choice) {
 document.all.myHR.setAttribute(select.name, choice)
 }
 }
}
</SCRIPT>
</HEAD>

<BODY>
<H1>HR Object Properties</H1>

<P>Here is the HR element you will be controlling:</P>
<HR ID="myHR">
<FORM>
Select an alignment:

 <OPTION VALUE=4>4 Pixels</OPTION>
 <OPTION VALUE=10>10 Pixels</OPTION>
</SELECT>

Select a rule width:
<SELECT NAME="width" onChange="setHRAttr(this)">
 <OPTION></OPTION>
 <OPTION VALUE="100%">100% (Default)</OPTION>
 <OPTION VALUE="80%">80%</OPTION>
 <OPTION VALUE=300>300 Pixels </OPTION>
</SELECT>
</BODY>
</HTML>

```

## color

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

See Listing 19-2 earlier in this chapter for an example of values that can be used to set the `color` property of an HR element object.

**noShade**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

See Listing 19-2 earlier in this chapter for an example of values that can be used to set the `noShade` property of an HR element object. Because of the buggy behavior associated with setting this property, adjusting the property in the example has unexpected (and usually undesirable) consequences.

**size**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

See Listing 19-2 earlier in this chapter for an example of values that can be used to set the `size` property of an HR element object.

**width**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

See Listing 19-2 earlier in this chapter for an example of values that can be used to set the `width` property of an HR element object.

# MARQUEE Element Object

## Properties

### behavior

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 19-3 contains a page that demonstrates the changes to several MARQUEE element object properties: `behavior`, `bgColor`, `direction`, `scrollAmount`, and `scrollDelay`. This page and scripts are intended only for IE4+. See the description of Listing 19-1 for details on the attribute setting script.

#### Listing 19-3: Controlling MARQUEE Object Properties

```
<HTML>
<HEAD>
<TITLE>MARQUEE Object Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// one function does all!
function setMARQUEEAttr(select) {
 if (document.all && document.all.myMARQUEE) {
 var choice = select.options[select.selectedIndex].value
 if (choice) {
 document.all.myMARQUEE.setAttribute(select.name, choice)
 }
 }
}
</SCRIPT>
</HEAD>

<BODY>
<H1>MARQUEE Object Properties</H1>

<HR>
<MARQUEE ID="myMARQUEE" WIDTH=400 HEIGHT=24>This is the MARQUEE element object

 <OPTION VALUE=125>Long</OPTION>
</SELECT>
</BODY>
</HTML>
```

## bgColor

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

See Listing 19-3 earlier in this chapter for an example of how to apply values to the `bgColor` property.

## direction

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

See Listing 19-3 earlier in this chapter for an example of how to apply values to the `direction` property.

## scrollAmount scrollDelay

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

See Listing 19-3 earlier in this chapter for an example of how to apply values to the `scrollAmount` and `scrollDelay` properties.

## Methods

`start()`  
`stop()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 19-3 earlier in this chapter for examples of both the `start()` and `stop()` methods, which are invoked in event handlers of separate controlling buttons on the page. Notice, too, that when you have the behavior set to `slide`, stopping and restarting the MARQUEE does not cause the scroll action to start from a blank region.

## Range Object

### Properties

`collapsed`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `collapsed` property. Reload the page and assign a new range to the a global variable by typing the following statement into the top text box:

```
a = document.createRange()
```

Next, set the range to encompass a node:

```
a.selectNode(document.body)
```

Enter `a.collapsed` into the top text box. The expression returns `false` because the end points of the range are not the same.

## commonAncestorContainer

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `commonAncestorContainer` property. Reload the page and assign a new range to the `a` global variable by typing the following statement into the top text box:

```
a = document.createRange()
```

Now set the start point to the beginning of the contents of the `myEM` element and set the end point to the end of the surrounding `myP` element:

```
a.setStartBefore(document.getElementById("myEM").firstChild)
a.setEndAfter(document.getElementById("myP").lastChild)
```

Verify that the text range is set to encompass content from the `myEM` node (the word “all”) and end of `myP` nodes:

```
a.toString()
```

Verify, too, that the two end point containers are different nodes:

```
a.startContainer.tagName
a.endContainer.tagName
```

Finally, see what node contains both of these two end points:

```
a.commonAncestorContainer.id
```

The result is the `myP` element, which both the `myP` and `myEM` nodes have in common.

## endContainer startContainer

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `endContainer` and `startContainer` properties. Reload the page and assign a new range to the `a` global variable by typing the following statement into the top text box:

```
a = document.createRange()
```

Now set the range to encompass the `myEM` element:

```
a.selectNode(document.getElementById("myEM"))
```

Inspect the containers for both the start and end points of the selection:

```
a.startContainer.id
a.endContainer.id
```

The range encompasses the entire `myEM` element, so the start and end points are outside of the element. Therefore, the container of both start and end points is the `myP` element that also surrounds the `myEM` element.

## endOffset startOffset

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with the `endOffset` and `startOffset` properties, following similar paths you just saw in the description.

Reload the page and assign a new range to the a global variable by typing the following statement into the top text box:

```
a = document.createRange()
```

Now set the range to encompass the myEM element and then move the start point outward to a character within the myP element's text node:

```
a.selectNode(document.getElementById("myEM"))
a.setStart(document.getElementById("myP").firstChild, 7)
```

Inspect the node types of the containers for both the start and end points of the selection:

```
a.startContainer.nodeType
a.endContainer.nodeType
```

The startContainer node type is 3 (text node), while the endContainer node type is 1 (element). Now inspect the offsets for both the start and end points of the selection:

```
a.startOffset
a.endOffset
```

## Methods

cloneContents()  
cloneRange()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

When Netscape outfits the NN6 browser with the cloneContents() method, use The Evaluator (Chapter 13) to see the method in action. Begin by creating a new range object that contains the text of the myP paragraph element.

```
a = document.createRange()
a.selectNode(document.getElementById("myP"))
```

Next, clone the original range and preserve the copy in variable `b`:

```
b = a.cloneContents()
```

Move the original range so that it is an insertion point at the end of the body by first expanding it to encompass the entire body and then collapse it to the end

```
a.selectNode(document.body)
a.collapse(false)
```

Now, insert the copy at the very end of the body:

```
a.insertBefore(b)
```

If you scroll to the bottom of the page, you see a copy of the text.

See the description of the `compareBoundaryPoints()` method later in this chapter to see an example of the `cloneRange()` method.

## `collapse([startBoolean])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

See Listings 19-11 and 15-14 to see the `collapse()` method at work (albeit with the IE `TextRange` object).

## `compareBoundaryPoints(typeInteger, sourceRangeRef)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

The page rendered by Listing 19-4 lets you experiment with text range comparisons in NN6+. The bottom paragraph contains a `SPAN` element that has a `Range` object

assigned to its nested text node after the page loads (in the `init()` function). That fixed range becomes a solid reference point for you to use while you select text in the paragraph.

**Note**

Unfortunately, the `window` object method that converts a user selection into an object is not connected correctly in the first release of NN6. Even if it were, the inverted values returned by the `compareBoundaryPoints()` method would give you incorrect results. Try this example on subsequent versions of NN6.

After you make a selection, all four versions of the `compareBoundaryPoints()` method run to compare the start and end points of the fixed range against your selection. One column of the results table shows the raw value returned by the `compareBoundaryPoints()` method, while the third column puts the results into plain language.

To see how this page works, begin by selecting the first word of the fixed text range (carefully drag the selection from the first red character). You can see that the starting positions of both ranges are the same, because the returned value is 0. Because all of the invocations of the `compareBoundaryPoints()` method are on the fixed text range, all comparisons are from the point of view of that range. Thus, the first row of the table for the `START_TO_END` parameter indicates that the start point of the fixed range comes before the end point of the selection, yielding a return value of -1.

Other selections to make include:

- ♦ Text that starts before the fixed range and ends inside the range
- ♦ Text that starts inside the fixed range and ends beyond the range
- ♦ Text that starts and ends precisely at the fixed range boundaries
- ♦ Text that starts and ends before the fixed range
- ♦ Text that starts after the fixed range

Study the returned values and the plain language results and see how they align with the selection you made.

### Listing 19-4: Lab for NN6 `compareBoundaryPoints()` Method

## createContextualFragment("text")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to create a document fragment and replace an existing document tree node with the fragment. Begin by creating the range and fragment:

```

a = document.createRange()
a.selectNode(document.body)
b = a.createContextualFragment("a bunch of
")

```

This fragment consists of a SPAN element node with a text node nested inside. At this point, you can inspect the properties of the document fragment by entering `b` into the bottom text box.

To replace the `myEM` element on the page with this new fragment, use the `replaceChild()` method on the enclosing `myP` element:

```
document.getElementById("myP").replaceChild(b, document.getElementById("myEM"))
```

The fragment now becomes a legitimate child node of the `myP` element and can be referenced like any node in the document tree. For example, if you enter the following statement into the top text box of The Evaluator, you can retrieve a copy of the text node inside the new SPAN element:

```
document.getElementById("myP").childNodes[1].firstChild.nodeValue
```

## deleteContents()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with deleting contents of both a text node and a complete element node. Begin by creating a text range for the text node inside the `myEM` element (enter the third statement, which wraps below, as one continuous expression):

```
a = document.createRange()
a.setStart(document.getElementById("myEM").firstChild, 0)
a.setEnd(document.getElementById("myEM").lastChild,
 document.getElementById("myEM").lastChild.length)
```

Verify the makeup of the range by entering `a` into the bottom text box and inspect its properties. Both containers are text nodes (they happen to be the same text node), and offsets are measured by character positions.

Now, delete the contents of the range:

```
a.deleteContents()
```

The italicized word “all” is gone from the tree, but the `myEM` element is still there. To prove it, put some new text inside the element:

```
document.getElementById("myEM").innerHTML = "a band of "
```

The italic style of the EM element applies to the text, as it should.

Next, adjust the range boundaries to include the `myEM` element tags, as well:

```
a.selectNode(document.getElementById("myEM"))
```

Inspect the `Range` object’s properties again by entering `a` into the bottom text box. The container nodes are the `P` element that surrounds the EM element; the offset values are measured in nodes. Delete the range’s contents:

```
a.deleteContents()
```

Not only is the italicized text gone, but the `myEM` element is gone, too. The `myP` element now has but one child node, the text node inside. The following entries into the top text box of The Evaluator verify this fact:

```
document.getElementById("myP").childNodes.length
document.getElementById("myP").childNodes[0].nodeValue
```

If you try this example in early versions of NN6, however, you see that the `deleteContents()` method also removes the text node following the `myEM` element. This is buggy behavior, demonstrating that the method works best on text nodes, rather than elements.

## extractContents()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

When Netscape outfits the NN6 browser with the `extractContents()` method, use The Evaluator (Chapter 13) to see how the method works. Begin by creating a new range object that contains the text of the `myP` paragraph element.

```
a = document.createRange()
a.selectNode(document.getElementById("myP"))
```

Next, extract the original range's content and preserve the copy in variable `b`:

```
b = a.extractContents()
```

Move the original range so that it is an insertion point at the end of the body by first expanding it to encompass the entire body and then collapse it to the end

```
a.selectNode(document.body)
a.collapse(false)
```

Now, insert the extracted fragment at the very end of the body:

```
a.insertNode(b)
```

If you scroll to the bottom of the page, you see a copy of the text.

`insertNode(nodeReference)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					

**Example**

Listing 19-5, which relies on `selection` and `Range` object features not implemented in the first release of NN6, demonstrates the `insertNode()` method plus some additional items from the NN6 `selection` object. The example even includes a rudimentary undo buffer for scripted changes to a text range. In the page generated by this listing, users can select any text in a paragraph and have the script automatically convert the text to all uppercase characters. The task of replacing a selection with other text requires several steps, starting with the selection, which is retrieved via the `window.getSelection()` method. After making sure the selection contains some text (that is, the selection isn't collapsed), the selection is preserved as a range object so that the starting text can be stored in a global variable (as a property of the `undoBuffer` global variable object). After that, the selection is deleted from the document tree, leaving the selection as a collapsed insertion point. A copy of that selection in the form of a range object is preserved in the `undoBuffer` object so that the undo script knows where to reinsert the original text. A new text node is created with an uppercase version of the original text, and, finally, the `insertNode()` method is invoked to stick the converted text into the collapsed range.

Undoing this operation works in reverse. Original locations and strings are copied from the `undoBuffer` object. After creating the range with the old start and end points (which represent a collapsed insertion point), the resurrected text (converted to a text node) is inserted into the collapsed range. For good housekeeping, the `undoBuffer` object is restored to its unused form.

**Listing 19-5: Inserting a Node into a Range**

```
<HTML>
<HEAD>
<TITLE>NN Selection Object Replacement</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var undoBuffer = {rng:null, txt:""}
function convertSelection() {
 var sel, grossRng, netRng, newText
 try {
 sel = window.getSelection()
```

```

 if (!sel.isCollapsed) {
 grossRng = sel.getRangeAt(0)
 undoBuffer.txt = grossRng.toString()
 sel.deleteFromDocument()
 netRng = sel.getRangeAt(0)
 undoBuffer.rng = netRng
 newText = document.createTextNode(undoBuffer.txt.toUpperCase())
 netRng.insertNode(newText)
 }
 }
 catch(err) {
 alert("Vital Range object services are not yet implemented in this
browser.")
 }
}
function undoConversion() {
 var rng, oldText
 if (undoBuffer.rng) {
 rng = document.createRange()
 rng.setStart(undoBuffer.rng.startParent, undoBuffer.rng.startOffset)
 rng.setEnd(undoBuffer.rng.endParent, undoBuffer.rng.endOffset)
 oldText = document.createTextNode(undoBuffer.txt)
 rng.insertNode(oldText)
 undoBuffer.rng = null
 undoBuffer.txt = ""
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1 ID="H1_1">NN6 Selection Object Replacement</H1>
<HR>

replaced by all uppercase versions of the selected text.</P>
<BUTTON onClick="undoConversion()">Undo Last</BUTTON>
<BUTTON onClick="location.reload(true)">Start Over</BUTTON>
</BODY>
</HTML>

```

## isValidFragment("HTMLText")

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

You can try the validity of any strings that you like in The Evaluator (Chapter 13). You will discover, however, that the object model can make a document fragment out of just about any string. For instance, if you attempt to create a document fragment out of some random text and an end tag, the document fragment will consist of a text node and an element node of the type indicated by the end tag.

`selectNode(nodeReference)`  
`selectNodeContents(nodeReference)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to see the behavior of both the `selectNode()` and `selectNodeContents()` methods work. Begin by creating a new range object.

```
a = document.createRange()
```

Set the range boundaries to include the `myP` element node:

```
a.selectNode(document.getElementById("myP"))
```

Enter `a` into the bottom text box to view the properties of the range. Notice that because the range has selected the entire paragraph node, the container of the range's start and end points is the `BODY` element of the page (the parent element of the `myP` element).

Now change the range so that it encompasses only the contents of the `myP` element:

```
a.selectNodeContents(document.getElementById("myP"))
```

Click the List Properties button to view the current properties of the range. The container of the range's boundary points is the `P` element that holds the element's contents.

```
setEnd(nodeReference, offset)
setStart(nodeReference, offset)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with both the `setStart()` and `setEnd()` methods. Begin by creating a new range object.

```
a = document.createRange()
```

For the first range, set the start and end points to encompass the second node (the `myEM` element) inside the `myP` element:

```
a.setStart(document.getElementById("myP"), 1)
a.setEnd(document.getElementById("myP"), 2)
```

The text encompassed by the range consists of the word “all” plus the trailing space that is contained by the `myEM` element. Prove this by entering the following statement into the top text box:

```
a.toString()
```

If you then click the Results box to the right of the word “all,” you see that the results contain the trailing space. Yet, if you examine the properties of the range (enter `a` into the bottom text box), you see that the range is defined as actually starting before the `myEM` element and ending after it.

Next, adjust the start point of the range to a character position inside the first text node of the `myP` element:

```
a.setStart(document.getElementById("myP").firstChild, 11)
```

Click the List Properties button to see that the `startContainer` property of the range is the text node, and that the `startOffset` measures the character position. All end boundary properties, however, have not changed. Enter `a.toString()` in the top box again to see that the range now encompasses text from two of the nodes inside the `myP` element.

You can continue to experiment by setting the start and end points to other element and text nodes on the page. After each adjustment, verify the properties of the `a` range object and the text it encompasses (via `a.toString()`).

```
setEndAfter(nodeReference)
setEndBefore(nodeReference)
setStartAfter(nodeReference)
setStartBefore(nodeReference)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) to experiment with all four methods. Begin by creating a new range object.

```
a = document.createRange()
```

For the first range, set the start and end points to encompass the `myEM` element inside the `myP` element:

```
a.setStartBefore(document.getElementById("myEM"))
a.setEndAfter(document.getElementById("myEM"))
```

The text encompassed by the range consists of the word “all” plus the trailing space that is contained by the `myEM` element. Prove this by entering the following statement into the top text box:

```
a.toString()
```

Next, adjust the start point of the range to the beginning of the first text node of the `myP` element:

```
a.setStartBefore(document.getElementById("myP").firstChild)
```

Enter `a` into the bottom text box to see that the `startParent` property of the range is the `P` element node, while the `endParent` property points to the `EM` element.

You can continue to experiment by setting the start and end points to before and after other element and text nodes on the page. After each adjustment, verify the properties of the `a` range object and the text it encompasses (via `a.toString()`).

## surroundContents(*nodeReference*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Listing 19-6, which relies on `selection` and `Range` object features not implemented in the first release of NN6, demonstrates how the `surroundContents()` method wraps a range inside a new element. As the page loads, a global variable (`newSpan`) stores a `SPAN` element that is used as a prototype for elements to be used as new surrounding parent nodes. When you select text in either of the two paragraphs, the selection is converted to a range. The `surroundContents()` method then wraps the range with the `newSpan` element. Because that `SPAN` element has a class name of `hilite`, the element and its contents pick up the style sheet properties as defined for that class selector.

### Listing 19-6: Using the `Range.surroundContents()` Method

```
<HTML>
<HEAD>
<TITLE>Range.surroundContents() Method</TITLE>
<STYLE TYPE="text/css">
.hilite {background-color:yellow; color:red; font-weight:bold}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
var newSpan = document.createElement("SPAN")
newSpan.className = "hilite"

function highlightSelection() {
 var sel, rng
 try {
 sel = window.getSelection()
 if (!sel.isCollapsed) {
 rng = sel.getRangeAt(0)
 rng.surroundContents(newSpan.cloneNode(false))
 }
 }
 catch(err) {
 alert("Vital Range object services are not yet implemented in this
browser.")
 }
}
```

*Continued*

## Listing 19-6 (continued)

```

 }
 }
</SCRIPT>
</HEAD>
<BODY>
<H1>Range.surroundContents() Method</H1>
<HR>
<P onMouseUp="highlightSelection()">These paragraphs
contain text that you can select. Selections are surrounded
by SPAN elements that share a stylesheet class selector
for special font and display characteristics.</P>

<P onMouseUp="highlightSelection()">Lorem ipsum dolor
sit amet, consectetur adipiscing elit,
sed do eiusmod tempor incididunt ut labore et dolore magna
aliqua. Ut enim adminim veniam, quis nostrud exercitation
ullamco laboris nisi ut aliquip ex ea commodo consequat.</P>
</BODY>
</HTML>

```

## toString()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

**Example**

Use The Evaluator (Chapter 13) to see the results of the `toString()` method. Enter the following sequence of statements into the top text box:

```

a = document.createRange()
a.selectNode(document.getElementById("myP"))
a.toString()

```

If you type only `a` into the top text box, you see the text contents of the range, but don't be fooled. Internal workings of The Evaluator attempt to evaluate any expression entered into that text field. Assigning a range object to a text box forces an internal application of the `toString()` method (just as the `Date` object does when you create a new object instance in The Evaluator).

# selection Object

## Properties

type

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Listing 19-7 contains a page that demonstrates several features of the `selection` object. When you make a selection with the Deselect radio button selected, you see the value of the `selection.type` property (in the statusbar) before and after the selection is deselected. After the selection goes away, the `type` property returns `None`.

### Listing 19-7: Using the `document.selection` Object

```
<HTML>
<HEAD>
<TITLE>selection Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function processSelection() {
 if (document.choices.process[0].checked) {
 status = "Selection is type: " + document.selection.type
 setTimeout("emptySelection()", 2000)
 } else if (document.choices.process[1].checked) {
 var rng = document.selection.createRange()
 document.selection.clear()
 }
}
function emptySelection() {
 document.selection.empty()
 status = "Selection is type: " + document.selection.type
}
</SCRIPT>
</HEAD>
<BODY>
<H1>IE selection Object</H1>
<HR>
```

*Continued*

`selection.type`

### Listing 19-7 (continued)

```

aliqua. Ut enim adminim veniam, quis nostrud exercitation ullamco laboris nisi
ut aliquip ex ea commodo consequat. Duis aute irure dolor in reprehenderit
involuptate velit esse cillum dolore eu fugiat nulla pariatur.
</BODY>
</HTML>
```

## Methods

### clear()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

See Listing 19-7 earlier in this chapter to see the `selection.clear()` method at work.

### createRange()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

**Example**

See Listings 15-36 and 15-45 to see the `selection.createRange()` method turn user selections into text ranges.

`empty()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

See Listing 19-7 earlier in this chapter to view the `selection.empty()` method at work.

## Text and TextNode Objects

### Properties

`data`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

In the Chapter 15 example for the `nodeValue` property used in a text replacement script, you can substitute the `data` property for `nodeValue` to accomplish the same result.

## Methods

```
appendData("text")
deleteData(offset, count)
insertData(offset, "text")
replaceData(offset, count, "text")
substringData(offset, count)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

The page created by Listing 19-8 is a working laboratory that you can use to experiment with the five data-related methods in NN6+. The text node that invokes the methods is a simple sentence in a P element. Each method has its own clickable button, followed by two or three text boxes into which you enter values for method parameters. Don't be put off by the length of the listing. Each method's operation is confined to its own function and is fairly simple.

Each of the data-related methods throws exceptions of different kinds. To help handle these errors gracefully, the method calls are wrapped inside a `try/catch` construction. All caught exceptions are routed to the `handleError()` function where details of the error are inspected and friendly alert messages are displayed to the user. See Chapter 39 for details on the `try/catch` approach to error handling in W3C DOM-capable browsers.

### Listing 19-8: Text object Data Method Laboratory

```
<HTML>
<HEAD>
<TITLE>Data Methods of a W3C Text Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function doAppend(form) {
 var node = document.getElementById("myP").firstChild
 var newString = form.appendStr.value
 try {
 node.appendData(newString)
 }
 catch(err) {
```

```
 handleError(err)
 }
}
function doDelete(form) {
 var node = document.getElementById("myP").firstChild
 var offset = form.deleteOffset.value
 var count = form.deleteCount.value
 try {
 node.deleteData(offset, count)
 }
 catch(err) {
 handleError(err)
 }
}
function doInsert(form) {
 var node = document.getElementById("myP").firstChild
 var offset = form.insertOffset.value
 var newString = form.insertStr.value
 try {
 node.insertData(offset, newString)
 }
 catch(err) {
 handleError(err)
 }
}

function doReplace(form) {
 var node = document.getElementById("myP").firstChild
 var offset = form.replaceOffset.value
 var count = form.replaceCount.value
 var newString = form.replaceStr.value
 try {
 node.replaceData(offset, count, newString)
 }
 catch(err) {
 handleError(err)
 }
}

function showSubstring(form) {
 var node = document.getElementById("myP").firstChild
 var offset = form.substrOffset.value
 var count = form.substrCount.value
 try {
 alert(node.substringData(offset, count))
 }
 catch(err) {
 handleError(err)
 }
}
```

*Continued*

## Listing 19-8 (continued)

```

// error handler for these methods
function handleError(err) {
 switch (err.name) {
 case "NS_ERROR_DOM_INDEX_SIZE_ERR":
 alert("The offset number is outside the allowable range.")
 break
 case "NS_ERROR_DOM_NOT_NUMBER_ERR":
 alert("Make sure each numeric entry is a valid number.")
 break
 default:
 alert("Double-check your text box entries.")
 }
}
</SCRIPT>
</HEAD>
<BODY>

</FORM>
</BODY>
</HTML>

```

## splitText(*offset*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	✓

### Example

Use The Evaluator (Chapter 13) to see the `splitText()` method in action. Begin by verifying that the `myEM` element has but one child node, and that its `nodeValue` is the string “all”:

```
document.getElementById("myEM").childNodes.length
document.getElementById("myEM").firstChild.nodeValue
```

Next, split the text node into two pieces after the first character:

```
document.getElementById("myEM").firstChild.splitText(1)
```

Two text nodes are now inside the element:

```
document.getElementById("myEM").childNodes.length
```

Each text node contains its respective portion of the original text:

```
document.getElementById("myEM").firstChild.nodeValue
document.getElementById("myEM").lastChild.nodeValue
```

If you are using NN6, now bring the text nodes back together:

```
document.getElementById("myEM").normalize()
document.getElementById("myEM").childNodes.length
```

At no time during these statement executions does the rendered text change.

# TextRange Object

## Properties

boundingHeight  
 boundingLeft  
 boundingTop  
 boundingWidth

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Listing 19-9 provides a simple playground to explore the four bounding properties (and two offset properties) of a `TextRange` object. As you select text in the big paragraph, the values of all six properties are displayed in the table. Values are also updated if you resize the window via an `onResize` event handler.

Notice, for example, if you simply click in the paragraph without dragging a selection, the `boundingWidth` property shows up as zero. This action is the equivalent of a `TextRange` acting as an insertion point.

### Listing 19-9: Exploring the Bounding TextRange Properties

```

<HTML>
<HEAD>
<TITLE>TextRange Object Dimension Properties</TITLE>
<STYLE TYPE="text/css">
TD {text-align:center}
.propName {font-family: Courier, monospace}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function setAndShowRangeData() {
 var range = document.selection.createRange()
 B1.innerText = range.boundingHeight
 B2.innerText = range.boundingWidth
 B3.innerText = range.boundingTop
 B4.innerText = range.boundingLeft
 B5.innerText = range.offsetTop
 }

```

## htmlText

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to investigate values returned by the `htmlText` property. Use the top text box to enter the following statements and see the values in the Results box.

Begin by creating a `TextRange` object for the entire body and store the range in local variable `a`:

```
a = document.body.createTextRange()
```

Next, use the `findText()` method to set the start and end points of the text range around the word “all,” which is an `EM` element inside the `myP` paragraph:

```
a.findText("all")
```

The method returns `true` (see the `findText()` method) if the text is found and the text range adjusts to surround it. To prove that the text of the text range is what you think it is, examine the `text` property of the range:

```
a.text
```

Because the text range encompasses all of the text of the element, the `htmlText` property contains the tags for the element as well:

```
a.htmlText
```

If you want to experiment by finding other chunks of text and looking at both the `text` and `htmlText` properties, first restore the text range to encompass the entire body with the following statement:

```
a.expand("textEdit")
```

You can read about the `expand()` method later in this chapter. In other tests, use `findText()` to set the range to “for all” and just “for al.” Then, see how the `htmlText` property exposes the `EM` element’s tags.

`text`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 19-11 later in this chapter for the `findText()` method to see the `text` property used to perform the replace action of a search-and-replace function.

## Methods

`collapse([startBoolean])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listings 19-11 and 15-14 to see the `collapse()` method at work.

`compareEndpoints("type", rangeRef)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

The page rendered by Listing 19-10 lets you experiment with text range comparisons. The bottom paragraph contains a SPAN element that has a `TextRange` object assigned to its text after the page loads (in the `init()` function). That fixed range becomes a solid reference point for you to use while you select text in the paragraph. After you make a selection, all four versions of the `compareEndpoints()` method run to compare the start and end points of the fixed range against your

selection. One column of the results table shows the raw value returned by the `compareEndPoints()` method, while the third column puts the results into plain language.

To see how this page works, begin by selecting the first word of the fixed text range (double-click the word). You can see that the starting positions of both ranges are the same, because the returned value is 0. Because all of the invocations of the `compareEndPoints()` method are on the fixed text range, all comparisons are from the point of view of that range. Thus, the first row of the table for the `StartToEnd` parameter indicates that the start point of the fixed range comes before the end point of the selection, yielding a return value of -1.

Other selections to make include:

- ♦ Text that starts before the fixed range and ends inside the range
- ♦ Text that starts inside the fixed range and ends beyond the range
- ♦ Text that starts and ends precisely at the fixed range boundaries
- ♦ Text that starts and ends before the fixed range
- ♦ Text that starts after the fixed range

Study the returned values and the plain language results and see how they align with the selection you make.

### Listing 19-10: Lab for `compareEndPoints()` Method

```
<HTML>
<HEAD>

</HTML>

```

## duplicate()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use [The Evaluator \(Chapter 13\)](#) to see how the `duplicate()` method works. Begin by creating a new `TextRange` object that contains the text of the `myP` paragraph element.

```

a = document.body.createTextRange()
a.moveToElementText(myP)

```

Next, clone the original range and preserve the copy in variable `b`:

```
b = a.duplicate()
```

The method returns no value, so don't be alarmed by the "undefined" that appears in the Results box. Move the original range so that it is an insertion point at the end of the body by first expanding it to encompass the entire body, and then collapse it to the end:

```
a.expand("textedit")
a.collapse(false)
```

Now, insert the copy at the very end of the body:

```
a.text = b.text
```

If you scroll to the bottom of the page, you'll see a copy of the text.

```
execCommand("commandName"[, UIFlag[, value]])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to see how to copy a text range's text into the client computer's Clipboard. Begin by setting the text range to the `myP` element:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
```

Now use `execCommand()` to copy the range into the Clipboard:

```
a.execCommand("Copy")
```

To prove that the text is in the Clipboard, click the bottom text field and choose Paste from the Edit menu (or type `Ctrl+V`).

```
expand("unit")
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

You can find examples of the `expand()` method in Listing 15-14.

```
findText("searchString" [, searchScope, flags])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

Listing 19-11 implements two varieties of text search and replace operation, while showing you how to include extra parameters for case-sensitive and whole word searches. Both approaches begin by creating a `TextRange` for the entire body, but they immediately shift the starting point to the beginning of the DIV element that contains the text to search.

One search and replace function prompts the user to accept or decline replacement for each instance of a found string. The `select()` and `scrollIntoView()` methods are invoked to help the user see what is about to be replaced. Notice that even when the user declines to accept the replacement, the text range is collapsed to the end of the found range so that the next search can begin after the previously found text. Without the `collapse()` method, the search can get caught in an infinite loop as it keeps finding the same text over and over (with no replacement made). Because no counting is required, this search and replace operation is implemented inside a `while` repeat loop.

The other search and replace function goes ahead and replaces every match and then displays the number of replacements made. After the loop exits (because there are no more matches), the loop counter is used to display the number of replacements made.

### Listing 19-11: Two Search and Replace Approaches (with Undo)

```
<HTML>
<HEAD>
<TITLE>TextRange.findText() Method</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

// global range var for use with Undo
var rng

// return findText() third parameter arguments
function getArgs(form) {
 var isCaseSensitive = (form.caseSensitive.checked) ? 4 : 0
 var isWholeWord = (form.wholeWord.checked) ? 2 : 0
 return isCaseSensitive ^ isWholeWord
}

// prompted search and replace
function sAndR(form) {
 var srchString = form.searchString.value
 var replString = form.replaceString.value
 if (srchString) {
 var args = getArgs(form)
 rng = document.body.createTextRange()
 rng.moveToElementText(rights)
 clearUndoBuffer()
 while (rng.findText(srchString, 10000, args)) {
 rng.select()
 rng.scrollIntoView()
 if (confirm("Replace?")) {
 rng.text = replString
 pushUndoNew(rng, srchString, replString)
 }
 rng.collapse(false)
 }
 }
}

// unprompted search and replace with counter
function sAndRCount(form) {
 var srchString = form.searchString.value
 var replString = form.replaceString.value
 var i
 if (srchString) {
 var args = getArgs(form)
 rng = document.body.createTextRange()
 rng.moveToElementText(rights)
 for (i = 0; rng.findText(srchString, 10000, args); i++) {
 rng.text = replString
 pushUndoNew(rng, srchString, replString)
 rng.collapse(false)
 }
 if (i > 1) {
 clearUndoBuffer()
 }
 }
}

---

Having a search and replace function available in a document is only one-half of the battle. The other half is offering the facilities to undo the changes. To that end, Listing 19-11 includes an undo buffer that accurately undoes only the changes made in the initial replacement actions.

The undo buffer stores its data in two global variables. The first, `origSearchString`, is simply the string used to perform the original search. This variable is the string that has to be put back in the places where it had been replaced. The second global variable is an array that stores `TextRange` bookmarks (see `getBookmark()` later in this chapter). These references are string values that don't mean much to humans, but the browser can use them to recreate a range with its desired start and end point. Values for both the global search string and bookmark specifications are stored in calls to the `pushUndoNew()` method each time text is replaced.

A perhaps unexpected action of setting the `text` property of a text range is that the start and end points collapse to the end of the new text. Because the stored bookmark must include the replaced text as part of its specification, the start point of the current range must be adjusted back to the beginning of the replacement text before the bookmark can be saved. Thus, the `pushUndoNew()` function receives the replacement text string so that the `moveStart()` method can be adjusted by the number of characters matching the length of the replacement string.

After all of the bookmarks are stored in the array, the undo action can do its job in a rather simple for loop inside the `undoReplace()` function. After verifying that the

undo buffer has data stored in it, the function loops through the array of bookmarks and replaces the bookmarked text with the old string. The benefit of using the bookmarks rather than using the replacement function again is that only those ranges originally affected by the search-and-replace operation are touched in the undo operation. For example, in this document if you replace a case-sensitive “states” with “States” two replacements are performed. At that point, however, the document has four instances of “States,” two of which existed before. Redoing the replacement function by inverting the search and replace strings would convert all four back to the lowercase version — not the desired effect.

## getBookmark()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 19-11 earlier in this chapter shows how the `getBookmark()` method is used to preserve specifications for text ranges so that they can be called upon again to be used to undo changes made to the text range. The `getBookmark()` method is used to save the snapshots, while the `moveToBookmark()` method is used during the undo process.

## inRange(*otherRangeRef*)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see the `inRange()` method in action. The following statements generate two distinct text ranges, one for the `myP` paragraph element and the other for the `myEM` element nested within.

```
a = document.body.createTextRange()
a.moveToElementText(myP)
b = document.body.createTextRange()
b.moveToElementText(myEM)
```

Because the `myP` text range is larger than the other, invoke the `inRange()` method on it, fully expecting the return value of `true`

```
a.inRange(b)
```

But if you switch the references, you see that the larger text range is not “in” the smaller one:

```
b.inRange(a)
```

## `isEqual(otherRangeRef)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to try the `isEqual()` method. Begin by creating two separate `TextRange` objects, one for the `myP` element and one for `myEM`.

```
a = document.body.createTextRange()
a.moveToElement(myP)
b = document.body.createTextRange()
b.moveToElement(myEM)
```

Because these two ranges encompass different sets of text, they are not equal, as the results show from the following statement:

```
a.isEqual(b)
```

But if you now adjust the first range boundaries to surround the `myEM` element, both ranges are the same values:

```
a.moveToElement(myEM)
a.isEqual(b)
```

## `move("unit"[, count])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `move()` method. To see how the method returns just the number of units it moves the pointer, begin by creating a text range and set it to enclose the `myP` element:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
```

Now enter the following statement to collapse and move the range backward by 20 words.

```
a.move("word", -20)
```

Continue to click the Evaluate button and watch the returned value in the Results box. The value shows 20 while it can still move backward by 20 words. But eventually the last movement will be some other value closer to zero. And after the range is at the beginning of the BODY element, the range can move no more in that direction, so the result is zero.

```
moveEnd("unit" [, count])
moveStart("unit" [, count])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `moveEnd()` and `moveStart()` methods. Begin by creating a text range and set it to enclose the `myEM` element:

```
a = document.body.createTextRange()
a.moveToElementText(myEM)
```

To help you see how movements of the pointers affect the text enclosed by the range, type `a` into the bottom text box and view all the properties of the text range. Note especially the `htmlText` and `text` properties.

Now enter the following statement to move the end of the range forward by one word.

```
a.moveEnd("word")
```

Click on the List Properties button to see that the text of the range now includes the word following the EM element. Try each of the following statements in the top text box and examine both the integer results and (by clicking the List Properties button) the properties of the range after each statement:

```
a.moveStart("word", -1)
a.moveEnd("sentence")
```

Notice that for a sentence, a default unit of 1 expands to the end of the current sentence. And if you move the start point backward by one sentence, you'll see that the lack of a period-ending sentence prior to the `myP` element causes strange results.

Finally, force the start point backward in increments of 20 words and watch the results as the starting point nears and reaches the start of the BODY:

```
a.moveStart("word", -20)
```

Eventually the last movement will be some other value closer to zero. And as soon as the range is at the beginning of the BODY element, the range can move no more in that direction, so the result is zero.

## `moveToBookmark("bookmarkString")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 19-11 earlier in this chapter shows how to use the `moveToBookmark()` method to restore a text range so that changes that created the state saved by the bookmark can be undone. The `getBookmark()` method is used to save the snapshots, while the `moveToBookmark()` method is used during the undo process.

## `moveToElementText(elementObjRef)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

A majority of examples for other `TextRange` object methods in this chapter use the `moveToElementText()` method. Listings 19-10 and 19-11 earlier in this chapter show the method within an application context.

## `moveToPoint(x, y)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator to see the `moveToPoint()` method in action. Begin by creating a text range for the entire BODY element:

```
a = document.body.createTextRange()
```

Now, invoke the `moveToPoint()` method to a location 100, 100, which turns out to be in the rectangle space of the Results textarea:

```
a.moveToPoint(100,100)
```

If you type `a` into the bottom text box and view the properties, both the `htmlText` and `text` properties are empty because the insertion point represents no visible text content. But if you gradually move, for example, the start point backward one character at a time, you will see the `htmlText` and `text` properties begin to fill in with the body text that comes before the TEXTAREA element, namely the “Results:” label and the `<BR>` tag between it and the TEXTAREA element. Enter the following statement into the top text box and click the Evaluate button several times.

```
a.moveStart("character", -1)
```

Enter `a` into the bottom text box after each evaluation to list the properties of the range.

## `parentElement()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `parentElement()` method. Begin by setting the text range to the `myEM` element:

```
a = document.body.createTextRange()
a.moveToElementText(myEM)
```

To inspect the object returned by the `parentElement()` method, enter the following statement in the lower text box:

```
a.parentElement()
```

If you scroll down to the `outerHTML` property, you see that the parent of the text range is the `myEM` element, tag and all.

Next, extend the end point of the text range by one word:

```
a.moveEnd("word")
```

Because part of the text range now contains text of the `myP` object, the `outerHTML` property of `a.parentElement()` shows the entire `myP` element and tags.

## `pasteHTML("HTMLText")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `pasteHTML()` method. The goal of the following sequence is to change the `<EM>` tag to a `<SPAN>` tag whose `STYLE` attribute sets the color of the original text that was in the `EM` element.

Begin by creating the text range and setting the boundaries to the `myEM` element:

```
a = document.body.createTextRange()
a.moveToElementText(myEM)
```

While you can pass the HTML string directly as a parameter to `pasteHTML()`, storing the HTML string in its own temporary variable may be more convenient (and more easily testable), such as:

```
b = "" + a.text + ""
```

Notice that we concatenate the text of the current text range, because it has not yet been modified. Now we can paste the new HTML string into the current text range

```
a.pasteHTML(b)
```

At this point the EM element is gone from the object model, and the SPAN element is in its place. Prove it to yourself by looking at the HTML for the myP element:

```
myP.innerHTML
```

As noted earlier, the `pasteHTML()` method is not the only way to insert or replace HTML in a document. This method makes excellent sense when the user selects some text in the document to be replaced, because you can use the `document.selection.createRange()` method to get the text range for the selection. But if you're not using text ranges for other related operations, consider the other generic object properties and methods available to you.

## select()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 19-11 earlier in this chapter for an example of the `select()` method in use.

## setEndPoint("type", otherRangeRef)

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator to experiment with the `setEndPoint()` method. Begin by creating two independent text ranges, one for the myP element and one for myEM:

```
a = document.body.createTextRange()
a.moveToElementText(myP)
b = document.body.createTextRange()
b.moveToElementText(myEM)
```

Before moving any end points, compare the HTML for each of those ranges:

```
a.htmlText
b.htmlText
```

Now, move the start point of the a text range to the end point of the b text range:

```
a.setEndPoint("StartToEnd", b)
```

If you now view the HTML for the a range,

```
a.htmlText
```

you see that the `<P>` tag of the original a text range is nowhere to be found. This demonstration is a good lesson to use the `setEndPoint()` method primarily if you are concerned only with visible body text being inside ranges, rather than an element with its tags.

## TextRectangle Object

### Properties

```
bottom
left
right
top
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Listing 19-12 lets you click one of four nested elements to see how the `TextRectangle` is treated. When you click one of the elements, that element's `TextRectangle` dimension properties are used to set the size of a positioned element that highlights the space of the rectangle. Be careful not to confuse the visible rectangle object that you see on the page with the abstract `TextRectangle` object that is associated with each of the clicked elements.

An important part of the listing is the way the action of sizing and showing the positioned element is broken out as a separate function (`setHiliter()`) from the one that is the `onClick` event handler function (`handleClick()`). This is done so that the `onResize` event handler can trigger a script that gets the current rectangle for the last element clicked, and the positioned element can be sized and moved to maintain the highlight of the same text. As an experiment, try removing the `onResize` event handler from the `<BODY>` tag and watch what happens to the highlighted rectangle after you resize the browser window: the rectangle that represents the `TextRectangle` remains unchanged and loses track of the abstract `TextRectangle` associated with the actual element object.

### Listing 19-12: Using the `TextRectangle` Object Properties

```
<HTML>
<HEAD>
<TITLE>TextRectangle Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// preserve reference to last clicked elem so resize can re-use it
var lastElem
// TextRectangle left tends to be out of registration by a couple of pixels
var rectLeftCorrection = 2

// process mouse click
function handleClick() {
 var elem = event.srcElement
 if (elem.className && elem.className == "sample") {
 // set hiliter element only on a subset of elements
 lastElem = elem
 setHiliter()
 } else {
 // otherwise, hide the hiliter
 hideHiliter()
 }
}

function setHiliter() {
 if (lastElem) {
 var textRect = lastElem.getBoundingClientRect()
 hiliter.style.pixelTop = textRect.top + document.body.scrollTop
 hiliter.style.pixelLeft = textRect.left + document.body.scrollLeft -
 rectLeftCorrection
 hiliter.style.pixelHeight = textRect.bottom - textRect.top
 hiliter.style.pixelWidth = textRect.right - textRect.left
 hiliter.style.visibility = "visible"
 }
}

function hideHiliter() {
 hiliter.style.visibility = "hidden"
 lastElem = null
}
```

```

}
</SCRIPT>
</HEAD>
<BODY onClick="handleClick()" onResize="setHiliter()">
<H1>TextRectangle Object</H1>
<HR>
<P>Click on any of the four colored elements in the paragraph below and watch
the highlight rectangle adjust itself to the element's TextRectangle object.

<P CLASS="sample">Lorem ipsum dolor sit amet, <SPAN CLASS="sample"
STYLE="color:red">consectetur adipisicing elit, sed do eiusmod tempor
incididunt ut labore et dolore magna aliqua. Ut enim adminim veniam,
quis nostrud exercitation ullamco laboris nisi ut aliquip ex ea commodo
consequat. Duis aute irure dolor in reprehenderit involuptate velit esse cillum

<DIV ID="hiliter" STYLE="position:absolute; background-color:salmon; z-index:-1;
visibility:hidden"></DIV>
</BODY>
</HTML>

```

---

## Chapter 22 Examples

The following sections contain examples from Chapter 22, “Image, Area, and Map Objects.”

### Image and IMG Element Objects

#### Properties

`align`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Listing 22-1 enables you to choose from the different `align` property values as they influence the layout of an image whose HTML is embedded inline with some other text. Resize the window to see different perspectives on word-wrapping on a page and their effects on the alignment choices. Not all browsers provide distinctive alignments for each choice, so experiment in multiple supported browsers.

### Listing 22-1: Testing an Image's align Property

```
<HTML>
<HEAD>
<TITLE>IMG align Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">

function setAlignment(sel) {
 document.myIMG.align = sel.options[sel.selectedIndex].text
}
</SCRIPT>
</HEAD>
<BODY>
<H1>IMG align Property</H1>
<HR>
<FORM>
Choose the image alignment:
<SELECT onChange="setAlignment(this)">
 <OPTION>absbottom
 <OPTION>absmiddle
 <OPTION>baseline
 <OPTION SELECTED >bottom
 <OPTION >left
 <OPTION>middle
 <OPTION>right
 <OPTION>texttop
 <OPTION>top
</SELECT>
</FORM>
<HR>
<P>Lorem ipsum dolor sit amet, consectetur adipiscing elit,
sed do eiusmod tempor incididunt ut labore et dolore magna
aliqua.
Ut enim adminim veniam, quis nostrud exercitation
ullamco laboris nisi ut aliquip ex ea commodo consequat.</P>
</BODY>
</HTML>
```

## alt

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to assign a string to the `alt` property of the `document.myIMG` image on the page. First, assign a nonexistent image to the `src` property to remove the existing image:

```
document.myIMG.src = "fred.gif"
```

Scroll down to the image, and you can see a space for the image. Now, assign a string to the `alt` property:

```
document.myIMG.src = "Fred\'s face"
```

The extra backslash is required to escape the apostrophe inside the string. Scroll down to see the new `alt` text in the image space.

## border

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

Feel free to experiment with the `document.myIMG.border` property for the image in The Evaluator (Chapter 13) by assigning different integer values to the property.

## complete

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

## Example

To experiment with the `image.complete` property, quit and relaunch your browser before loading Listing 22-2 (in case the images are in memory cache). As each image loads, click the “Is it loaded yet?” button to see the status of the `complete` property for the image object. The value is `false` until the loading finishes; then, the value becomes `true`. The arch image is the bigger of the two image files. You may have to quit and relaunch your browser between trials to clear the arch image from the cache (or empty the browser’s memory cache). If you experience difficulty with this property in your scripts, try adding an `onLoad` event handler (even if it is empty, as in Listing 22-2) to your `<IMG>` tag.

### Listing 22-2: Scripting `image.complete`

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript1.1">
function loadIt(theImage,form) {
 form.result.value = ""
 document.images[0].src = theImage
}
function checkLoad(form) {
 form.result.value = document.images[0].complete
}
</SCRIPT>
</HEAD>
<BODY>

<FORM>
<INPUT TYPE="button" VALUE="Load keyboard"
onClick="loadIt('cpu2.gif',this.form)">
<INPUT TYPE="button" VALUE="Load arch"
onClick="loadIt('arch.gif',this.form)"><P>
<INPUT TYPE="button" VALUE="Is it loaded yet?" onClick="checkLoad(this.form)">
<INPUT TYPE="text" NAME="result">
</FORM>
</BODY>
</HTML>
```

## dynsrc

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

To swap between still and video sources, simply empty the opposite property. Listing 22-3 shows a simplified example that swaps between one fixed image and one video image. This listing exhibits most of the bugs associated with changing between static image and video sources described in the text.

### Listing 22-3: Changing Between Still and Motion Images

```

<HTML>
<HEAD>
<TITLE>IMG dynsrc Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">

var trainImg = new Image(160,120)
trainImg.src = "amtrak.jpg"
trainImg.dynsrc = "amtrak.mpg"

function setLoop() {
 var selector = document.forms[0].looper
 document.myIMG.loop = selector.options[selector.selectedIndex].value
}

function setImage(type) {
 if (type == "jpg") {
 document.myIMG.dynsrc = ""
 document.myIMG.src = trainImg.src
 } else {
 document.myIMG.src = ""
 document.myIMG.start = "fileopen"
 setLoop()
 document.myIMG.dynsrc = trainImg.dynsrc
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>IMG dynsrc Property</H1>
<HR>
<FORM>
Choose image type:
<INPUT TYPE="radio" NAME="imgGroup" CHECKED onClick="setImage('jpg')">Still
<INPUT TYPE="radio" NAME="imgGroup" onClick="setImage('mpg')">Video
<P>Play video how many times after loading:
<SELECT NAME="looper" onChange="setLoop()">
 <OPTION VALUE=1 SELECTED>Once
 <OPTION VALUE=2>Twice
 <OPTION VALUE=-1>Continuously

```

*Continued*

**Listing 22-3 (continued)**

```
</SELECT></P>
</FORM>
<HR>

</BODY>
</HTML>
```

If you don't explicitly set the `start` property to `fileopen` (as shown in Listing 22-3), users of IE for the Macintosh have to double-click (IE4) or click (IE5) the movie image to make it run.

`fileCreatedDate`  
`fileModifiedDate`  
`fileSize`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

These properties are similar to the same-named properties of the `document` object. You can see these properties in action in Listing 18-4. Make a copy of that listing, and supply an image before modifying the references from the `document` object to the image object to see how these properties work with the `IMG` element object.

`height`  
`width`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `height` and `width` properties. Begin retrieving the default values by entering the following two statements into the top text box:

```
document.myIMG.height
document.myIMG.width
```

Increase the height of the image from its default 90 to 180:

```
document.myIMG.height = 180
```

If you scroll down to the image, you see that the image has scaled in proportion. Next, exaggerate the width:

```
document.myIMG.width = 400
```

View the resulting image.

`hspace`  
`vspace`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to experiment with the `hspace` and `vspace` properties. Begin by noticing that the image near the bottom of the page has no margins specified for it and is flush left with the page. Now assign a horizontal margin spacing of 30 pixels:

```
document.myIMG.hspace = 30
```

The image has shifted to the right by 30 pixels. An invisible margin also exists to the right of the image.

## i sMap

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The image in The Evaluator page is not defined as an image map. Thus, if you type the following statement into the top text box, the property returns `false`:

```
document.myIMG.isMap
```

## loop

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 22-3 for the `dynsrc` property to see the `loop` property in action.

## lowsrc

## lowSrc

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

See Listing 22-5 for the image object's `onLoad` event handler to see how the source-related properties affect event processing.

## name

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	(✓)		✓	✓	✓

**Example**

You can use The Evaluator to examine the value returned by the `name` property of the image on that page. Enter the following statement into the top text box:

```
document.myIMG.name
```

Of course, this is redundant because the name is part of the reference to the object.

## nameProp

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

**Example**

You can use The Evaluator to compare the results of the `src` and `nameProp` properties in IE5+/Windows. Enter each of the following statements into the top text box:

```
document.myIMG.src
document.myIMG.nameProp
```

## protocol

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

You can use The Evaluator to examine the `protocol` property of the image on the page. Enter the following statement into the top text box:

```
document.myIMG.protocol
```

## src

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓	(✓)		✓	✓	✓

## Example

In the following example (Listing 22-4), you see a few applications of image objects. Of prime importance is a comparison of how precached and regular images feel to the user. As a bonus, you see an example of how to set a timer to automatically change the images displayed in an image object. This feature is a popular request among sites that display advertising banners.

As the page loads, a global variable is handed an array of image objects. Entries of the array are assigned string names as index values ("desk1", "desk2", and so on). The intention is that these names ultimately will be used as addresses to the array entries. Each image object in the array has a URL assigned to it, which precaches the image.

The page (see Figure 22-1) includes two IMG elements: one that displays noncached images and one that displays cached images. Under each image is a SELECT element that you can use to select one of four possible image files for each element. The `onChange` event handler for each SELECT list invokes a different function to change the noncached (`loadIndividual()`) or cached (`loadCached()`) images. Both of these functions take as their single parameter a reference to the form that contains the SELECT elements.

To cycle through images at five-second intervals, the `checkTimer()` function looks to see if the timer check box is checked. If so, the `selectedIndex` property of the cached image SELECT control is copied and incremented (or reset to zero if the index is at the maximum value). The SELECT element is adjusted, so you can now invoke the `loadCached()` function to read the currently selected item and set the image accordingly.

For some extra style points, the `<BODY>` tag includes an `onUnload` event handler that invokes the `resetSelects()` function. This general-purpose function loops

through all forms on the page and all elements within each form. For every SELECT element, the `selectedIndex` property is reset to zero. Thus, if a user reloads the page, or returns to the page via the Back button, the images start in their original sequence. An `onLoad` event handler makes sure that the images are in sync with the SELECT choices and the `checkTimer()` function is invoked with a five-second delay. Unless the timer check box is checked, however, the cached images don't cycle.

### Listing 22-4: A Scripted Image Object and Rotating Images

```

<HTML>
<HEAD>
<TITLE>Image Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// global declaration for 'desk' images array
var imageDB
// pre-cache the 'desk' images
if (document.images) {
 // list array index names for convenience
 var deskImages = new Array("desk1", "desk2", "desk3", "desk4")
 // build image array and pre-cache them
 imageDB = new Array(4)
 for (var i = 0; i < imageDB.length ; i++) {
 imageDB[deskImages[i]] = new Image(120,90)
 imageDB[deskImages[i]].src = deskImages[i] + ".gif"
 }
}
// change image of 'individual' image
function loadIndividual(form) {
 if (document.images) {
 var gifName =
form.individual.options[form.individual.selectedIndex].value
 document.thumbnail1.src = gifName + ".gif"
 }
}
// change image of 'cached' image
function loadCached(form) {
 if (document.images) {
 var gifIndex = form.cached.options[form.cached.selectedIndex].value
 document.thumbnail2.src = imageDB[gifIndex].src
 }
}
// if switched on, cycle 'cached' image to next in queue
function checkTimer() {
 if (document.images && document.Timer.timerBox.checked) {
 var gifIndex = document.selections.cached.selectedIndex
 if (++gifIndex > imageDB.length - 1) {
 gifIndex = 0
 }
 }
}

```

*Continued*

## Listing 22-4: A Scripted Image Object and Rotating Images

```

 }
 document.selections.cached.selectedIndex = gifIndex
 loadCached(document.selections)
 var timeoutID = setTimeout("checkTimer()",5000)
 }
}
// reset form controls to defaults on unload
function resetSelects() {
 for (var i = 0; i < document.forms.length; i++) {
 for (var j = 0; j < document.forms[i].elements.length; j++) {
 if (document.forms[i].elements[j].type == "select-one") {
 document.forms[i].elements[j].selectedIndex = 0
 }
 }
 }
}
// get things rolling
function init() {
 loadIndividual(document.selections)
 loadCached(document.selections)
 setTimeout("checkTimer()",5000)
}
</SCRIPT>
</HEAD>

<BODY onLoad="init()" onUnload="resetSelects ()">

**Figure 22-1:** The image object demonstration page (*Images* (c) Aris Multimedia Entertainment, Inc. 1994)

## start

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 22-3 earlier in this chapter for an example of how you can use the `start` property with a page that loads a movie clip into an `IMG` element object.

x

y

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

If you want to scroll the document so that the link is a few pixels below the top of the window, use a statement such as this:

```
window.scrollTo(document.images[0].x, (document.images[0].y - 3))
```

## Event handlers

onAbort

onError

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

## Example

Listing 22-5 includes an `onAbort` event handler. If the images already exist in the cache, you must quit and relaunch the browser to try to stop the image from loading. In that example, I provide a reload option for the entire page. How you handle the exception depends a great deal on your page design. Do your best to smooth over any difficulties that users may encounter.

## onLoad

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

## Example

Quit and restart your browser to get the most from Listing 22-5. As the document first loads, the `LOWSRC` image file (the picture of pencil erasers) loads ahead of the computer keyboard image. When the erasers are loaded, the `onLoad` event handler writes “done” to the text field even though the main image is not loaded yet. You can experiment further by loading the arch image. This image takes longer to load, so the `LOWSRC` image (set on the fly, in this case) loads way ahead of it.

### Listing 22-5: The Image `onLoad` Event Handler

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function loadIt(theImage,form) {
 if (document.images) {
 form.result.value = ""
 document.images[0].lowsrc = "desk1.gif"
 document.images[0].src = theImage
 }
}
function checkLoad(form) {
 if (document.images) {
 form.result.value = document.images[0].complete
 }
}
function signal() {
 if(confirm("You have stopped the image from loading. Do you want to try
again?")) {
```

*Continued*

## Listing 22-5 (continued)

```

 location.reload()
 }
}
</SCRIPT>
</HEAD>
<BODY>
<IMG SRC="cpu2.gif" LOWSRC="desk4.gif" WIDTH=120 HEIGHT=90
onLoad="if (document.forms[0].result) document.forms[0].result.value='done'"
onAbort="signal()">
<FORM>
<INPUT TYPE="button" VALUE="Load keyboard"
onClick="loadIt('cpu2.gif',this.form)">
<INPUT TYPE="button" VALUE="Load arch"
onClick="loadIt('arch.gif',this.form)"><P>
<INPUT TYPE="button" VALUE="Is it loaded yet?" onClick="checkLoad(this.form)">
<INPUT TYPE="text" NAME="result">
</FORM>
</BODY>
</HTML>

```

## AREA Element Object

### Properties

coords

shape

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

See Listing 22-7 for a demonstration of the `coords` and `shape` properties in the context of scripting MAP element objects.

# MAP Element Object

## Property

areas

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Listing 22-7 demonstrates how to use scripting to replace the AREA element objects inside a MAP element. The scenario is that the page loads with one image of a computer keyboard. This image is linked to the `keyboardMap` client-side image map, which specifies details for three hot spots on the image. If you then switch the image displayed in that IMG element, scripts change the `useMap` property of the IMG element object to point to a second MAP that has specifications more suited to the desk lamp in the second image. Roll the mouse pointer atop the images, and view the URLs associated with each area in the statusbar (for this example, the URLs do not lead to other pages).

Another button on the page, however, invokes the `makeAreas()` function (not working in IE5/Mac), which creates four new AREA element objects and (through DOM-specific pathways) adds those new area specifications to the image. If you roll the mouse atop the image after the function executes, you can see that the URLs now reflect those of the new areas. Also note the addition of a fourth area.

### Listing 22-7: Modifying AREA Elements on the Fly

```
<HTML>
<HEAD>
<TITLE>MAP Element Object</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// generate area elements on the fly
function makeAreas() {
 document.myIMG.src = "desk3.gif"
 // build area element objects
 var area1 = document.createElement("AREA")
 area1.href = "Script-Made-Shade.html"
 area1.shape = "polygon"
```

*Continued*

## Listing 22-7 (continued)

```

area1.coords = "52,28,108,35,119,29,119,8,63,0,52,28"
var area2 = document.createElement("AREA")
area2.href = "Script-Made-Base.html"
area2.shape = "rect"
area2.coords = "75,65,117,87"
var area3 = document.createElement("AREA")
area3.href = "Script-Made-Chain.html"
area3.shape = "polygon"
area3.coords = "68,51,73,51,69,32,68,51"
var area4 = document.createElement("AREA")
area4.href = "Script-Made-Emptyness.html"
area4.shape = "rect"
area4.coords = "0,0,50,120"
// stuff new elements into MAP child nodes
if (document.all) {
 // works for IE4+
 document.all.lampMap.areas.length = 0
 document.all.lampMap.areas[0] = area1
 document.all.lampMap.areas[1] = area2
 document.all.lampMap.areas[2] = area3
 document.all.lampMap.areas[3] = area4
} else if (document.getElementById) {
 // NN6 adheres to node model
 var mapObj = document.getElementById("lamp_map")
 while (mapObj.childNodes.length) {
 mapObj.removeChild(mapObj.firstChild)
 }
 mapObj.appendChild(area1)
 mapObj.appendChild(area2)
 mapObj.appendChild(area3)
 mapObj.appendChild(area4)
 // workaround NN6 display bug
 document.myIMG.style.display = "inline"
}

function changeToKeyboard() {
 document.myIMG.src = "cpu2.gif"
 document.myIMG.useMap = "#keyboardMap"

## Chapter 23 Examples

The following section contains examples from Chapter 23, “The Form and Related Objects.”

## FORM Object

### Properties

action

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The following statement assigns a `mailto:` URL to the first form of a page:

```
document.forms[0].action = "mailto:jdoe@giantco.com"
```

## elements

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The document in Listing 23-2 demonstrates a practical use of the `elements` property. A form contains four fields and some other elements mixed in between (see Figure 23-2). The first part of the function that acts on these items repeats through all the elements in the form to find out which ones are text box objects and which text box objects are empty. Notice how I use the `type` property to separate text box objects from the rest, even when radio buttons appear amid the fields. If one field has nothing in it, I alert the user and use that same index value to place the insertion point at the field with the field's `focus()` method.

### Listing 23-2: Using the `form.elements` Array

```
<HTML>
<HEAD>
<TITLE>Elements Array</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function verifyIt() {
 var form = document.forms[0]
 for (i = 0; i < form.elements.length; i++) {
 if (form.elements[i].type == "text" && form.elements[i].value == ""){
 alert("Please fill out all fields.")
 form.elements[i].focus()
 break
 }
 // more tests
 }
 // more statements
}
</SCRIPT>
</HEAD>
```

```
<BODY>
<FORM>
Enter your first name:<INPUT TYPE="text" NAME="firstName"><P>
Enter your last name:<INPUT TYPE="text" NAME="lastName"><P>
<INPUT TYPE="radio" NAME="gender">Male
<INPUT TYPE="radio" NAME="gender">Female <P>
Enter your address:<INPUT TYPE="text" NAME="address"><P>
Enter your city:<INPUT TYPE="text" NAME="city"><P>
<INPUT TYPE="checkbox" NAME="retired">I am retired
</FORM>
<FORM>
<INPUT TYPE="button" NAME="act" VALUE="Verify" onClick="verifyIt()">
</FORM>
</BODY>
</HTML>
```

**Figure 23-2:** The elements array helps find text fields for validation.

## encoding enctype

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

If you need to modify the first form in a document so that the content is sent in non-URL-encoded text at the user's request, the statement is:

```
document.forms[0].encoding = "text/plain"
```

## length

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to determine the number of form controls in the first form of the page. Enter the following statement into the top text box:

```
document.forms[0].length
```

## method

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

If you need to modify the first form in a document so that the content is sent via the POST method, the statement is:

```
document.forms[0].method = "POST"
```

## target

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

If you want to direct the response from the first form's CGI to a new window (rather than the target specified in the form's tag), use this statement:

```
document.forms[0].target = "_blank"
```

## Methods

### reset()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

In Listing 23-3, I assign the act of resetting the form to the HREF attribute of a link object (that is attached to a graphic called `reset.jpg`). I use the `javascript: URL` to invoke the `reset()` method for the form directly (in other words, without doing it via function). Note that the form's action in this example is to a nonexistent URL. If you click the Submit icon, you receive an "unable to locate" error from the browser.

#### Listing 23-3: `form.reset()` and `form.submit()` Methods

```
<HTML>
<HEAD>
<TITLE>Registration Form</TITLE>
</HEAD>
<BODY>
<FORM NAME="entries" METHOD=POST ACTION="http://www.u.edu/pub/cgi-bin/register">
Enter your first name:<INPUT TYPE="text" NAME="firstName"><P>
```

*Continued*

**Listing 23-3 (continued)**

```

Enter your last name:<INPUT TYPE="text" NAME="lastName"><P>
Enter your address:<INPUT TYPE="text" NAME="address"><P>
Enter your city:<INPUT TYPE="text" NAME="city"><P>
<INPUT TYPE="radio" NAME="gender" CHECKED>Male
<INPUT TYPE="radio" NAME="gender">Female <P>
<INPUT TYPE="checkbox" NAME="retired">I am retired
</FORM>
<P>
<IMG SRC="submit.jpg" HEIGHT=25
WIDTH=100 BORDER=0>
<IMG SRC="reset.jpg" HEIGHT=25
WIDTH=100 BORDER=0>
</BODY>
</HTML>

```

**submit()**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

Consult Listing 23-3 for an example of using the `submit()` method from outside of a form.

**Event handlers****onReset**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

## Example

Listing 23-4 demonstrates one way to prevent accidental form resets or submissions. Using standard Reset and Submit buttons as interface elements, the `<FORM>` object definition includes both event handlers. Each event handler calls its own function that offers a choice for users. Notice how each event handler includes the word `return` and takes advantage of the Boolean values that come back from the `confirm()` method dialog boxes in both functions.

### Listing 23-4: The `onReset` and `onSubmit` Event Handlers

```
<HTML>
<HEAD>
<TITLE>Submit and Reset Confirmation</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function allowReset() {
 return window.confirm("Go ahead and clear the form?")
}
function allowSend() {
 return window.confirm("Go ahead and mail this info?")
}
</SCRIPT>
</HEAD>
<BODY>
<FORM METHOD=POST ENCTYPE="text/plain" ACTION="mailto:trash4@dannyg.com"
onReset="return allowReset()" onSubmit="return allowSend()">
Enter your first name:<INPUT TYPE="text" NAME="firstName"><P>
Enter your last name:<INPUT TYPE="text" NAME="lastName"><P>
Enter your address:<INPUT TYPE="text" NAME="address"><P>
Enter your city:<INPUT TYPE="text" NAME="city"><P>
<INPUT TYPE="radio" NAME="gender" CHECKED>Male
<INPUT TYPE="radio" NAME="gender">Female <P>
<INPUT TYPE="checkbox" NAME="retired">I am retired<P>
<INPUT TYPE="reset">
<INPUT TYPE="submit">
</FORM>
</BODY>
</HTML>
```

## onSubmit

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See Listing 23-4 for an example of trapping a submission via the `onSubmit` event handler.

## LABEL Element Object

### Property

#### `htmlFor`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

### Example

The following statement uses W3C DOM-compatible syntax (IE5+ and NN6) to assign a form control reference to the `htmlFor` property of a label:

```
document.getElementById("myLabel").htmlFor = document.getElementById("myField")
```

## Chapter 24 Examples

The following sections contain examples from Chapter 24, “Button Objects.”

# The BUTTON Element Object and the Button, Submit, and Reset Input Objects

## Properties

form

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The following function fragment receives a reference to a button element as the parameter. The button reference is needed to decide which branch to follow; then the form is submitted.

```
function setAction(btn) {
 if (btn.name == "normal") {
 btn.form.action = "cgi-bin/normal.pl"
 } else if (btn.name == "special") {
 btn.form.action = "cgi-bin/specialHandling.pl"
 }
 btn.form.submit()
}
```

Notice how this function doesn't have to worry about the form reference, because its job is to work with whatever form encloses the button that triggers this function. Down in the form, two buttons invoke the same function. Only their names ultimately determine the precise processing of the button click:

```
<FORM>
...
<INPUT TYPE="button" NAME="normal" VALUE="Regular Handling"
onClick="setAction(this)">
<INPUT TYPE="button" NAME="special" VALUE="Special Handling"
onClick="setAction(this)">
</FORM>
```

## name

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

See the example for the `form` property earlier in this chapter for a practical application of the `name` property.

## value

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

In the following excerpt, the statement toggles the label of a button from “Play” to “Stop” except in NN/Mac through NN4:

```
var btn = document.forms[0].controlButton
btn.value = (btn.value == "Play") ? "Stop" : "Play"
```

**Methods**

## click()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

The following statement demonstrates how to script a click action on a button form control named `sender`:

```
document.forms[0].sender.click()
```

## Event handlers

### onClicK

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listing 24-1 demonstrates not only the `onClicK` event handler of a button but also how you may need to extract a particular button's `name` or `value` properties from a general-purpose function that services multiple buttons. In this case, each button passes its own object as a parameter to the `displayTeam()` function. The function then displays the results in an alert dialog box. A real-world application would probably use a more complex `if...else` decision tree to perform more sophisticated actions based on the button clicked (or use a `switch` construction on the `btn.value` expression for NN4+ and IE4+).

#### Listing 24-1: Three Buttons Sharing One Function

```
<HTML>
<HEAD>
<TITLE>Button Click</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function displayTeam(btn) {
 if (btn.value == "Abbott") {alert("Abbott & Costello")}
 if (btn.value == "Rowan") {alert("Rowan & Martin")}
 if (btn.value == "Martin") {alert("Martin & Lewis")}
}
</SCRIPT>
</HEAD>

<BODY>
Click on your favorite half of a popular comedy team:<P>
<FORM>
<INPUT TYPE="button" VALUE="Abbott" onClick="displayTeam(this)">
<INPUT TYPE="button" VALUE="Rowan" onClick="displayTeam(this)">
<INPUT TYPE="button" VALUE="Martin" onClick="displayTeam(this)">
</FORM>
</BODY>
</HTML>
```

# Checkbox Input Object

## Properties

### checked

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The simple example in Listing 24-2 passes a form object reference to the JavaScript function. The function, in turn, reads the `checked` value of the form's checkbox object (`checkThis.checked`) and uses its Boolean value as the test result for the `if...else` construction.

#### Listing 24-2: The `checked` Property as a Conditional

```
<HTML>
<HEAD>
<TITLE>Checkbox Inspector</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function inspectBox(form) {
 if (form.checkThis.checked) {
 alert("The box is checked.")
 } else {
 alert("The box is not checked at the moment.")
 }
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<INPUT TYPE="checkbox" NAME="checkThis">Check here<P>
<INPUT TYPE="button" NAME="boxChecker" VALUE="Inspect Box"
onClick="inspectBox(this.form)">
</FORM>
</BODY>
</HTML>
```

## defaultChecked

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The function in Listing 24-3 (this fragment is not in the CD-ROM listings) is designed to compare the current setting of a checkbox against its default value. The `if` construction compares the current status of the box against its default status. Both are Boolean values, so they can be compared against each other. If the current and default settings don't match, the function goes on to handle the case in which the current setting is other than the default.

#### Listing 24-3: Examining the defaultChecked Property

```
function compareBrowser(thisBox) {
 if (thisBox.checked != thisBox.defaultChecked) {
 // statements about using a different set of HTML pages
 }
}
```

## value

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The scenario for the skeleton HTML page in Listing 24-4 is a form with a checkbox whose selection determines which of two actions to follow for submission to the server. After the user clicks the Submit button, a JavaScript function examines the checkbox's `checked` property. If the property is `true` (the button is checked), the script sets the `action` property for the entire form to the content of the `value` property—thus influencing where the form goes on the server side. If you try this

listing on your computer, the result you see varies widely with the browser version you use. For most browsers, you see some indication (an error alert or other screen notation) that a file with the name `primaryURL` or `alternateURL` doesn't exist. Unfortunately, IE5.5/Windows does not display the name of the file that can't be opened. Try the example in another browser if you have one. The names and the error message come from the submission process for this demonstration.

### Listing 24-4: Adjusting a CGI Submission Action

```
<HTML>
<HEAD>
<TITLE>Checkbox Submission</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function setAction(form) {
 if (form.checkThis.checked) {
 form.action = form.checkThis.value
 } else {
 form.action = "file://primaryURL"
 }
 return true
}
</SCRIPT>
</HEAD>
<BODY>
<FORM METHOD="POST" ACTION="">
<INPUT TYPE="checkbox" NAME="checkThis" VALUE="file://alternateURL">Use
alternate<P>
<INPUT TYPE="submit" NAME="boxChecker" onClick="return setAction(this.form)">
</FORM>
</BODY>
</HTML>
```

## Event handlers

### onClick

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

The page in Listing 24-5 shows how to trap the click event in one checkbox to influence the visibility and display of other form controls. After you turn on the Monitor checkbox, a list of radio buttons for monitor sizes appears. Similarly, engaging the Communications checkbox makes two radio buttons visible. Your choice of radio button brings up one of two further choices within the same table cell.

Notice how the `toggle()` function was written as a generalizable function. This function can accept a reference to any checkbox object and any related span. If five more groups like this were added to the table, no additional functions would be needed.

In the `swap()` function, an application of a nested `if...else` shortcut construction is used to convert the Boolean values of the `checked` property to the strings needed for the `display` style property. The nesting is used to allow a single statement to take care of two conditions: the group of buttons to be controlled and the `checked` property of the button invoking the function. This function is not generalizable, because it contains explicit references to objects in the document. The `swap()` function can be made generalizable, but due to the special relationships between pairs of span elements (meaning one has to be hidden while the other displayed in its place), the function would require more parameters to fill in the blanks where explicit references are needed.

### Note

A rendering bug in NN6 causes the form controls in the lower right frame to lose their settings when the elements have their `display` style property set to `none`. The problem is related to the inclusion of P or similar block elements inside a table cell that contains controls. Therefore, if you uncheck and recheck the Communications checkbox in the example page, the previously displayed subgroup shows up even though no radio buttons are selected. You can script around this bug by preserving radio button settings in a global variable as you hide the group, and restoring the settings when you show the group again.

Syntax used to address elements here is the W3C DOM-compatible form, so this listing runs as is with IE5+ and NN6+. You can modify the listing to run in IE4 by adapting references to the `document.all` format.

## Listing 24-5: A Checkbox and an onClick event Handler

```
<HTML>
<HEAD>
<TITLE>Checkbox Event Handler</TITLE>
<STYLE TYPE="text/css">
#monGroup {visibility:hidden}
#comGroup {visibility:hidden}

## Radio Input Object

### Properties

checked

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listing 24-6 uses a repeat loop in a function to look through all buttons in the Stooges group in search of the checked button. After the loop finds the one whose checked property is `true`, it returns the value of the index. In one instance, that index value is used to extract the `value` property for display in the alert dialog box; in the other instance, the value helps determine which button in the group is next in line to have its checked property set to `true`.

**Listing 24-6: Finding the Selected Button in a Radio Group**

```

<HTML>
<HEAD>
<TITLE>Extracting Highlighted Radio Button</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function getSelectedButton(buttonGroup){
 for (var i = 0; i < buttonGroup.length; i++) {
 if (buttonGroup[i].checked) {
 return i
 }
 }
 return 0
}
function fullName(form) {
 var i = getSelectedButton(form.stooges)
 alert("You chose " + form.stooges[i].value + ".")
}
function cycle(form) {
 var i = getSelectedButton(form.stooges)
 if (i+1 == form.stooges.length) {
 form.stooges[0].checked = true
 } else {
 form.stooges[i+1].checked = true
 }
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Select your favorite Stooge:
<P><INPUT TYPE="radio" NAME="stooges" VALUE="Moe Howard" CHECKED>Moe
<INPUT TYPE="radio" NAME="stooges" VALUE="Larry Fine" >Larry
<INPUT TYPE="radio" NAME="stooges" VALUE="Curly Howard" >Curly
<INPUT TYPE="radio" NAME="stooges" VALUE="Shemp Howard" >Shemp</P>
<P><INPUT TYPE="button" NAME="Viewer" VALUE="View Full Name..."
onClick="fullName(this.form)"></P>
<P><INPUT TYPE="button" NAME="Cycler" VALUE="Cycle Buttons"
onClick="cycle(this.form)"> </P>
</FORM>
</BODY>
</HTML>

```

## defaultChecked

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

In the script fragment of Listing 24-7 (not among the CD-ROM files), a function is passed a reference to a form containing the Stooges radio buttons. The goal is to see, in as general a way as possible (supplying the radio group name where needed), if the user changed the default setting. Looping through each of the radio buttons, you look for the one whose `CHECKED` attribute is set in the `<INPUT>` definition. With that index value (`i`) in hand, you then look to see if that entry is still checked. If not (notice the `!` negation operator), you display an alert dialog box about the change.

### Listing 24-7: Has a Radio Button Changed?

```
function groupChanged(form) {
 for (var i = 0; i < form.stooges.length; i++) {
 if (form.stooges[i].defaultChecked) {
 if (!form.stooges[i].checked) {
 alert("This radio group has been changed.")
 }
 }
 }
}
```

## length

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See the loop construction within the function of Listing 24-7 for one way to apply the `length` property.

## value

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

Listing 24-6 earlier in this chapter demonstrates how a function extracts the `value` property of a radio button to display otherwise hidden information stored with a button. In this case, it lets the alert dialog box show the full name of the selected Stooge.

**Event handlers**

## onClick

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

Every time a user clicks one of the radio buttons in Listing 24-8, he or she sets a global variable to `true` or `false`, depending on whether the person is a Shemp lover. This action is independent of the action that is taking place if the user clicks on the View Full Name button. An `onUnLoad` event handler in the `<BODY>` definition triggers a function that displays a message to Shemp lovers just before the page clears (click the browser's Reload button to leave the current page prior to reloading). Here I use an initialize function triggered by `onLoad` so that the current radio button selection sets the global value upon a reload.

**Listing 24-8: An onClick event Handler for Radio Buttons**

```
<HTML>
<HEAD>
<TITLE>Radio Button onClick Handler</TITLE>
<SCRIPT LANGUAGE="JavaScript">
```

```

var ShempOPhile = false
function initValue() {
 ShempOPhile = document.forms[0].stooges[3].checked
}
function fullName(form) {
 for (var i = 0; i < form.stooges.length; i++) {
 if (form.stooges[i].checked) {
 break
 }
 }
 alert("You chose " + form.stooges[i].value + ".")
}
function setShemp(setting) {
 ShempOPhile = setting
}
function exitMsg() {
 if (ShempOPhile) {
 alert("You like SHEMP?")
 }
}
</SCRIPT>
</HEAD>

<BODY onLoad="initValue()" onUnload="exitMsg()">
<FORM>
Select your favorite Stooge:<P>
<INPUT TYPE="radio" NAME="stooges" VALUE="Moe Howard" CHECKED
onClick="setShemp(false)">Moe
<INPUT TYPE="radio" NAME="stooges" VALUE="Larry Fine"
onClick="setShemp(false)">Larry
<INPUT TYPE="radio" NAME="stooges" VALUE="Curly Howard"
onClick="setShemp(false)">Curly
<INPUT TYPE="radio" NAME="stooges" VALUE="Shemp Howard"
onClick="setShemp(true)">Shemp<P>
<INPUT TYPE="button" NAME="Viewer" VALUE="View Full Name..."
onClick="fullName(this.form)">
</FORM>
</BODY>
</HTML>

```

---

See also Listing 24-5 for further examples of scripting `onClick` event handlers for radio buttons — this time to hide and show related items in a form.

## Chapter 25 Examples

The following sections contain examples from Chapter 25, “Text-Related Form Objects.”

### Text Input Object

#### Properties

`defaultValue`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

#### Example

Important: Listings 25-1, 25-2, and 25-3 feature a form with only one text INPUT element. The rules of HTML forms say that such a form submits itself if the user presses the Enter key whenever the field has focus. Such a submission to a form whose action is undefined causes the page to reload, thus stopping any scripts that are running at the time. FORM elements for of these example listings contain an `onSubmit` event handler that both blocks the submission and attempts to trigger the text box `onChange` event handler to run the demonstration script. In some browsers, such as IE5/Mac, you may have to press the Tab key or click outside of the text box to trigger the `onChange` event handler after you enter a new value.

Listing 25-1 has a simple form with a single field that has a default value set in its tag. A function (`resetField()`) restores the contents of the page’s lone field to the value assigned to it in the `<INPUT>` definition. For a single-field page such as this, defining a `TYPE="reset"` button or calling `form.reset()` works the same way because such buttons reestablish default values of all elements of a form. But if you want to reset only a subset of fields in a form, follow the example button and function in Listing 25-1.

#### Listing 25-1: Resetting a Text Object to Default Value

```
<HTML>
<HEAD>
<TITLE>Text Object DefaultValue</TITLE>
```

```

<SCRIPT LANGUAGE="JavaScript">
function upperMe(field) {
 field.value = field.value.toUpperCase()
}
function resetField(form) {
 form.converter.value = form.converter.defaultValue
}
</SCRIPT>
</HEAD>

<BODY>
<FORM onSubmit="window.focus(); return false">
Enter lowercase letters for conversion to uppercase: <INPUT TYPE="text"
NAME="converter" VALUE="sample" onChange="upperMe(this)">
<INPUT TYPE="button" VALUE="Reset Field"
onClick="resetField(this.form)">
</FORM>
</BODY>
</HTML>

```

## form

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The following function fragment receives a reference to a text element as the parameter. The text element reference is needed to decide which branch to follow; then the form is submitted.

```

function setAction(fld) {
 if (fld.value.indexOf("@") != -1) {
 fld.form.action = "mailto:" + fld.value
 } else {
 fld.form.action = "cgi-bin/normal.pl"
 }
 fld.form.submit()
}

```

Notice how this function doesn't have to worry about the form reference, because its job is to work with whatever form encloses the text field that triggers this function.

## maxLength

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to experiment with the `maxLength` property. The top text field has no default value, but you can temporarily set it to only a few characters and see how it affects entering new values:

```
document.forms[0].input.maxLength = 3
```

Try typing into the field to see the results of the change. To restore the default value, reload the page.

## name

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Consult Listing 25-2 later in this chapter, where I use the text object's name, `converter`, as part of the reference when assigning a value to the field. To extract the name of a text object, you can use the property reference. Therefore, assuming that your script doesn't know the name of the first object in the first form of a document, the statement is

```
var objectName = document.forms[0].elements[0].name
```

## readOnly

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Use The Evaluator (Chapter 13) to set the bottom text box to be read-only. Begin by typing anything you want in the bottom text box. Then enter the following statement into the top text box:

```
document.forms[0].inspector.readOnly = true
```

While existing text in the box is selectable (and therefore can be copied into the clipboard), it cannot be modified or removed.

## size

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

## Example

Resize the bottom text box of The Evaluator (Chapter 13) by entering the following statements into the top text box:

```
document.forms[0].inspector.size = 20
document.forms[0].inspector.size = 400
```

Reload the page to return the size back to normal (or set the value to 80).

## value

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

## Example

As a demonstration of how to retrieve and assign values to a text object, Listing 25-2 shows how the action in an `onChange` event handler is triggered. Enter any lowercase letters into the field and click out of the field. I pass a reference to the entire form object as a parameter to the event handler. The function extracts the value, converts it to uppercase (using one of the JavaScript string object methods), and assigns it back to the same field in that form.

**Listing 25-2: Getting and Setting a Text Object's Value**

```

<HTML>
<HEAD>
<TITLE>Text Object Value</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function upperMe(form) {
 inputStr = form.converter.value
 form.converter.value = inputStr.toUpperCase()
}
</SCRIPT>
</HEAD>

<BODY>
<FORM onSubmit="window.focus(); return false">
Enter lowercase letters for conversion to uppercase: <INPUT TYPE="text"
NAME="converter" VALUE="sample" onChange="upperMe(this.form)">
</FORM>
</BODY>
</HTML>

```

I also show two other ways to accomplish the same task, each one more efficient than the previous example. Both utilize the shortcut object reference to get at the heart of the text object. Listing 25-3 passes the text object — contained in the `this` reference — to the function handler. Because that text object contains a complete reference to it (out of sight, but there just the same), you can access the `value` property of that object and assign a string to that object's `value` property in a simple assignment statement.

**Listing 25-3: Passing a Text Object (as `this`) to the Function**

```

<HTML>
<HEAD>
<TITLE>Text Object Value</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function upperMe(field) {
 field.value = field.value.toUpperCase()
}
</SCRIPT>
</HEAD>

<BODY>
<FORM onSubmit="window.focus(); return false">
Enter lowercase letters for conversion to uppercase: <INPUT TYPE="text"
NAME="converter" VALUE="sample" onChange="upperMe(this)">
</FORM>

```

```
</BODY>
</HTML>
```

Yet another way is to deal with the field values directly in an embedded event handler — instead of calling an external function (which is easier to maintain because all scripts are grouped together in the Head). With the function removed from the document, the event handler attribute of the `<INPUT>` tag changes to do all the work:

```
<INPUT TYPE="text" NAME="converter" VALUE="sample"
 onChange="this.value = this.value.toUpperCase()">
```

The right-hand side of the assignment expression extracts the current contents of the field and (with the help of the `toUpperCase()` method of the string object) converts the original string to all uppercase letters. The result of this operation is assigned to the `value` property of the field.

The application of the `this` keyword in the previous examples may be confusing at first, but these examples represent the range of ways in which you can use such references effectively. Using `this` by itself as a parameter to an object's event handler refers only to that single object — a text object in Listing 25-3. If you want to pass along a broader scope of objects that contain the current object, use the `this` keyword along with the outer object layer that you want. In Listing 25-2, I sent a reference to the entire form along by specifying `this.form` — meaning the form that contains “this” object, which is being defined in the line of HTML code.

At the other end of the scale, you can use similar-looking syntax to specify a particular property of the `this` object. Thus, in the last example, I zeroed in on just the `value` property of the current object being defined — `this.value`. Although the formats of `this.form` and `this.value` appear the same, the fact that one is a reference to an object and the other just a value can influence the way your functions work. When you pass a reference to an object, the function can read and modify properties of that object (as well as invoke its functions); but when the parameter passed to a function is just a property value, you cannot modify that value without building a complete reference to the object and its value.

## Methods

### `blur()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The following statement invokes the `blur()` method on a text box named `vanishText`:

```
document.forms[0].vanishText.blur()
```

## focus()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See Listing 25-4 for an example of an application of the `focus()` method in concert with the `select()` method.

## select()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

A click of the Verify button in Listing 25-4 performs a validation on the contents of the text box, making sure the entry consists of all numbers. All work is controlled by the `checkNumeric()` function, which receives a reference to the field needing inspection as a parameter. Because of the way the delayed call to the `doSelection()` function has to be configured, various parts of what will become a valid reference to the form are extracted from the field's and form's properties. If the validation (performed in the `isNumber()` function) fails, the `setSelection()` method is invoked after an artificial delay of zero milliseconds. As goofy as this sounds, this method is all that IE needs to recover from the display and closure of the alert dialog box. Because the first parameter of the `setTimeout()` method must be a string, the example assembles a string invocation of the `setSelection()` function via string versions of the form and field names. All that the `setSelection()` function does is focus and select the field whose reference is passed as a parameter. This function is now generalizable to work with multiple text boxes in a more complex form.

**Listing 25-4: Selecting a Field**

```
<HTML>
<HEAD>
<TITLE>Text Object Select/Focus</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// general purpose function to see if a suspected numeric input is a number
function isNumber(inputStr) {
 for (var i = 0; i < inputStr.length; i++) {
 var oneChar = inputStr.charAt(i)
 if (oneChar < "0" || oneChar > "9") {
 alert("Please make sure entries are integers only.")
 return false
 }
 }
 return true
}
function checkNumeric(fld) {
 var inputStr = fld.value
 var fldName = fld.name
 var formName = fld.form.name
 if (isNumber(inputStr)) {
 // statements if true
 } else {
 setTimeout("doSelection(document." + formName + ". " + fldName + ")", 0)
 }
}

function doSelection(fld) {
 fld.focus()
 fld.select()
}
</SCRIPT>
</HEAD>

<BODY>
<FORM NAME="entryForm" onSubmit="return false">
Enter any positive integer: <INPUT TYPE="text" NAME="numeric"><P>
<INPUT TYPE="button" VALUE="Verify" onClick="checkNumeric(this.form.numeric)">
</FORM>
</BODY>
</HTML>
```

## Event handlers

onBlur  
onFocus  
onSelect

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

To demonstrate one of these event handlers, Listing 25-5 shows how you may use the window's statusbar as a prompt message area after a user activates any field of a form. When the user tabs to or clicks on a field, the prompt message associated with that field appears in the statusbar.

#### Listing 25-5: The onFocus event Handler

```
<HTML>
<HEAD>
<TITLE>Elements Array</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function prompt(msg) {
 window.status = "Please enter your " + msg + "."
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
Enter your first name:<INPUT TYPE="text" NAME="firstName"
onFocus="prompt('first name')"><P>
Enter your last name:<INPUT TYPE="text" NAME="lastName"
onFocus="prompt('last name')"><P>
Enter your address:<INPUT TYPE="text" NAME="address"
onFocus="prompt('address')"><P>
Enter your city:<INPUT TYPE="text" NAME="city" onFocus="prompt('city')"><P>
</FORM>
</BODY>
</HTML>
```

## onChange

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Whenever a user makes a change to the text in a field in Listing 25-6 and then either tabs or clicks out of the field, the change event is sent to that field, triggering the `onChange` event handler.

Because the form in Listing 25-6 has only one field, the example demonstrates a technique you can use that prevents a form from being “submitted” if the user accidentally presses the Enter key. The technique is as simple as defeating the submission via the `onSubmit` event handler of the form. At the same time, the `onSubmit` event handler invokes the `checkIt()` function, so that pressing the Enter key (as well as pressing Tab or clicking outside the field) triggers the function.

### Listing 25-6: Data Validation via an onChange event Handler

```

<HTML>
<HEAD>
<TITLE>Text Object Select/Focus</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// general purpose function to see if a suspected numeric input is a number
function isNumber(inputStr) {
 for (var i = 0; i < inputStr.length; i++) {
 var oneChar = inputStr.substring(i, i + 1)
 if (oneChar < "0" || oneChar > "9") {
 alert("Please make sure entries are numbers only.")
 return false
 }
 }
 return true
}
function checkIt(form) {
 inputStr = form.numeric.value
 if (isNumber(inputStr)) {
 // statements if true
 } else {
 form.numeric.focus()
 form.numeric.select()
 }
}

```

*Continued*

### Listing 25-6 (continued)

```
 }
 }
</SCRIPT>
</HEAD>

<BODY onSubmit="checkIt(this); return false">
<FORM>
 Enter any positive integer: <INPUT TYPE="text" NAME="numeric"
 onChange="checkIt(this.form)"><P>
</FORM>
</BODY>
</HTML>
```

## TEXTAREA Element Object

### Properties

cols  
rows

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator to play with the `cols` and `rows` property settings for the Results textarea on that page. Shrink the width of the textarea by entering the following statement into the top text box:

```
document.forms[0].output.cols = 30
```

And make the textarea one row deeper:

```
document.forms[0].output.rows++
```

## Methods

### createTextRange()

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

### Example

See the example for the `TextRange.move()` method in Chapter 19 to see how to control the text insertion pointer inside a `TEXTAREA` element.

## Chapter 26 Examples

The following sections contain examples from Chapter 26, “Select, Option, and FileUpload Objects.”

## SELECT Element Object

### Properties

#### length

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

See Listing 26-1 for an illustration of the way you use the `length` property to help determine how often to cycle through the repeat loop in search of selected items. Because the loop counter, `i`, must start at 0, the counting continues until the loop counter is one less than the actual length value (which starts its count with 1).

## multiple

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

The following statement toggles between single and multiple selections on a SELECT element object whose `SIZE` attribute is set to a value greater than 1:

```
document.forms[0].mySelect.multiple = !document.forms[0].mySelect.multiple
```

options[*index*]

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

See Listings 26-1 through 26-3 in the printed chapter for examples of how the `options` array references information about the options inside a SELECT element.

options[*index*].defaultSelected

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

The following statement preserves a Boolean value if the first option of the SELECT list is the default selected item:

```
var zeroIsDefault = document.forms[0].listName.options[0].defaultSelected
```

## options[*index*].index

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

The following statement assigns the index integer of the first option of a SELECT element named `listName` to a variable named `itemIndex`.

```
var itemIndex = document.forms[0].listName.options[0].index
```

## options[*index*].selected

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

To accumulate a list of all items selected by the user, the `seeList()` function in Listing 26-4 systematically examines the `options[index].selected` property of each item in the list. The text of each item whose `selected` property is `true` is appended to the list. I add the “\n ” inline carriage returns and spaces to make the list in the alert dialog box look nice and indented. If you assign other values to the `VALUE` attributes of each option, the script can extract the `options[index].value` property to collect those values instead.

### Listing 26-4: Cycling through a Multiple-Selection List

```
<HTML>
<HEAD>
<TITLE>Accessories List</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function seeList(form) {
 var result = ""
 for (var i = 0; i < form.acclist.length; i++) {
 if (form.acclist.options[i].selected) {
```

*Continued*

## Listing 26-4 (continued)

```

 result += "\n " + form.acclist.options[i].text
 }
}
 alert("You have selected:" + result)
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<P>Control/Command-click on all accessories you use:
<SELECT NAME="acclist" SIZE=9 MULTIPLE>
 <OPTION SELECTED>Color Monitor
 <OPTION>Modem
 <OPTION>Scanner
 <OPTION>Laser Printer
 <OPTION>Tape Backup
 <OPTION>MO Drive
 <OPTION>Video Camera
</SELECT> </P>
<P><INPUT TYPE="button" VALUE="View Summary..."
onClick="seeList(this.form)"></P>
</FORM>
</BODY>
</HTML>

```

options[*index*].text

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

To demonstrate the `text` property of an option, Listing 26-5 applies the text from a selected option to the `document.bgColor` property of a document in the current window. The color names are part of the collection built into all scriptable browsers; fortunately, the values are case-insensitive so that you can capitalize the color names displayed and assign them to the property.

**Listing 26-5: Using the options[index].text Property**

```

<HTML>
<HEAD>
<TITLE>Color Changer 1</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function seeColor(form) {
 var newColor = (form.colorsList.options[form.colorsList.selectedIndex].text)
 document.bgColor = newColor
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<P>Choose a background color:
<SELECT NAME="colorsList">
 <OPTION SELECTED>Gray
 <OPTION>Lime
 <OPTION>Ivory
 <OPTION>Red
</SELECT></P>
<P><INPUT TYPE="button" VALUE="Change It" onClick="seeColor(this.form)"></P>
</FORM>
</BODY>
</HTML>

```

**options[*index*].value**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

Listing 26-6 requires the option text that the user sees to be in familiar, multiple-word form. But to set the color using the browser's built-in color palette, you must use the one-word form. Those one-word values are stored in the `VALUE` attributes of each `<OPTION>` definition. The function then reads the `value` property, assigning it to the `bgColor` of the current document. If you prefer to use the hexadecimal triplet form of color specifications, those values are assigned to the `VALUE` attributes (`<OPTION VALUE="#e9967a">Dark Salmon`).

**Listing 26-6: Using the options[index].value Property**

```

<HTML>
<HEAD>
<TITLE>Color Changer 2</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function seeColor(form) {
 var newColor = (form.colorsList.options[form.colorsList.selectedIndex].value)
 document.bgColor = newColor
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<P>Choose a background color:
<SELECT NAME="colorsList">
 <OPTION SELECTED VALUE="cornflowerblue">Cornflower Blue
 <OPTION VALUE="darksalmon">Dark Salmon
 <OPTION VALUE="lightgoldenrodyellow">Light Goldenrod Yellow
 <OPTION VALUE="seagreen">Sea Green
</SELECT></P>
<P><INPUT TYPE="button" VALUE="Change It" onClick="seeColor(this.form)"></P>
</FORM>
</BODY>
</HTML>

```

## selectedIndex

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

In the `inspect()` function of Listing 26-7, notice that the value inside the options property index brackets is a reference to the object's `selectedIndex` property. Because this property always returns an integer value, it fulfills the needs of the index value for the options property. Therefore, if you select Green in the pop-up menu, `form.colorsList.selectedIndex` returns a value of 1; that reduces the rest of the reference to `form.colorsList.options[1].text`, which equals "Green."

**Listing 26-7: Using the selectedIndex Property**

```

<HTML>
<HEAD>
<TITLE>Select Inspector</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function inspect(form) {
 alert(form.colorsList.options[form.colorsList.selectedIndex].text)
}
</SCRIPT>
</HEAD>

<BODY>
<FORM>
<P><SELECT NAME="colorsList">
 <OPTION SELECTED>Red
 <OPTION VALUE="Plants"><I>Green</I>
 <OPTION>Blue
</SELECT></P>
<P><INPUT TYPE="button" VALUE="Show Selection" onClick="inspect(this.form)"></P>
</FORM>
</BODY>
</HTML>

```

**size**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

The following statement sets the number of visible items to 5:

```
document.forms[0].mySelect.size = 5
```

**value**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The function in Listing 26-6 that accesses the chosen value the long way can be simplified for newer browsers only with the following construction:

```
function seeColor(form) {
 document.bgColor = form.colorsList.value
}
```

## Methods

`item(index)`  
`namedItem("optionID")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

The following statement assigns an OPTION element reference to a variable:

```
var oneOption = document.forms[0].mySelect.namedItem("option3_2")
```

## Event handlers

`onChange`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listing 26-8 is a version of Listing 26-6 that invokes all action as the result of a user making a selection from the pop-up menu. The `onChange` event handler in the `<SELECT>` tag replaces the action button. For this application — when you desire a direct response to user input — an appropriate method is to have the action triggered from the pop-up menu rather than by a separate action button.

Notice two other important changes. First, the `SELECT` element now contains a blank first option. When a user visits the page, nothing is selected yet, so you should present a blank option to encourage the user to make a selection. The function also makes sure that the user selects one of the color-valued items before it attempts to change the background color.

Second, the `BODY` element contains an `onUnload` event handler that resets the form. The purpose behind this is that if the user navigates to another page and uses the Back button to return to the page, the script-adjusted background color does not persist. I recommend you return the `SELECT` element to its original setting. Unfortunately, the reset does not stick to the form in IE4 and IE5 for Windows (although this problem appears to be repaired in IE5.5). Another way to approach this issue is to use the `onLoad` event handler to invoke `seeColor()`, passing as a parameter a reference to the `SELECT` element. Thus, if the `SELECT` element choice persists, the background color is adjusted accordingly after the page loads.

### Listing 26-8: Triggering a Color Change from a Pop-Up Menu

```
<HTML>
<HEAD>
<TITLE>Color Changer 2</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function seeColor(list) {
 var newColor = (list.options[list.selectedIndex].value)
 if (newColor) {
 document.bgColor = newColor
 }
}
</SCRIPT>
</HEAD>

<BODY onUnload="document.forms[0].reset()">
<FORM>
<P>Choose a background color:
<SELECT NAME="colorsList" onChange="seeColor(this)">
 <OPTION SELECTED VALUE="">
 <OPTION VALUE="cornflowerblue">Cornflower Blue
 <OPTION VALUE="darksalmon">Dark Salmon
 <OPTION VALUE="lightgoldenrodyellow">Light Goldenrod Yellow
 <OPTION VALUE="seagreen">Sea Green
</SELECT></P>
</FORM>
</BODY>
</HTML>
```

## OPTION Element Object

### Properties

label

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	

### Example

The following statement modifies the text that appears as the selected text in a pop-up list:

```
document.forms[0].mySelect.options[3].label = "Widget 9000"
```

If this option is the currently selected one, the text on the pop-up list at rest changes to the new label.

## OPTGROUP Element Object

### Properties

label

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓				✓	

### Example

I present Listing 26-9 in the hope that Microsoft and Netscape will eventually eradicate the bugs that afflict their current implementations of the `label` property. When the feature works as intended, Listing 26-9 demonstrates how a script can alter the text of option group labels. This page is an enhanced version of the background color setters used in other examples of this chapter. Be aware that

IE5/Mac does not alter the last OPTGROUP element's label, and NN6 achieves only a partial change to the text displayed in the SELECT element.

### Listing 26-9: Modifying OPTGROUP Element Labels

```

<HTML>
<HEAD>
<TITLE>Color Changer 3</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var regularLabels = ["Reds","Greens","Blues"]
var naturalLabels = ["Apples","Leaves","Sea"]
function setRegularLabels(list) {
 var optGrps = list.getElementsByTagName("OPTGROUP")
 for (var i = 0; i < optGrps.length; i++) {
 optGrps[i].label = regularLabels[i]
 }
}
function setNaturalLabels(list) {
 var optGrps = list.getElementsByTagName("OPTGROUP")
 for (var i = 0; i < optGrps.length; i++) {
 optGrps[i].label = naturalLabels[i]
 }
}
function seeColor(list) {
 var newColor = (list.options[list.selectedIndex].value)
 if (newColor) {
 document.bgColor = newColor
 }
}
</SCRIPT>
</HEAD>

<BODY onUnload="document.forms[0].reset()">
<FORM>
<P>Choose a background color:
<SELECT name="colorsList" onChange="seeColor(this)">
 <OPTGROUP ID="optGrp1" label="Reds">
 <OPTION value="#ff9999">Light Red
 <OPTION value="#ff3366">Medium Red
 <OPTION value="#ff0000">Bright Red
 <OPTION value="#660000">Dark Red
 </OPTGROUP>
 <OPTGROUP ID="optGrp2" label="Greens">
 <OPTION value="#ccff66">Light Green
 <OPTION value="#99ff33">Medium Green
 <OPTION value="#00ff00">Bright Green
 <OPTION value="#006600">Dark Green
 </OPTGROUP>

```

*Continued*

**Listing 26-9 (continued)**

```

<OPTGROUP ID="optGrp3" label="Blues">
 <OPTION value="#ccffff">Light Blue
 <OPTION value="#66ccff">Medium Blue
 <OPTION value="#0000ff">Bright Blue
 <OPTION value="#000066">Dark Blue
</OPTGROUP>
</SELECT></P>
<P>
<INPUT TYPE="radio" NAME="labels" CHECKED
onClick="setRegularLabels(this.form.colorsList)">Regular Label Names
<INPUT TYPE="radio" NAME="labels"
onClick="setNaturalLabels(this.form.colorsList)">Label Names from Nature</P>
</FORM>
</BODY>
</HTML>

```

## Chapter 27 Examples

The following sections contain examples from Chapter 27, “Table and List Objects.”

## TABLE Element Object

### Properties

`align`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see the `align` property at work. The default value (`left`) is in force when the page loads. But you can shift the table to right-align with

the body by entering the following statement into the top text box for IE5+ and NN6+:

```
document.getElementById("myTable").align = "right"
```

## background

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Treat the background property of a table like you do the src property of an IMG element object. If you precache an image, you can assign the src property of the precached image object to the background property of the table for quick image changing. Such an assignment statement looks like the following:

```
document.all.myTable.background = imgArray["myTableAlternate"].src
```

## bgColor

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to assign a color to the table. After looking at the table to see its initial state, enter the following IE5+/NN6+ statement into the top text box:

```
document.getElementById("myTable").bgColor = "lightgreen"
```

When you look at the table again, you see that only some of the cells turned to green. This is because colors also are assigned to table elements nested inside the outermost table element, and the color specification closest to the actual element wins the context.

## border

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

To remove all traces of an outside border of a table (and, in some combinations of attributes of other table elements, borders between cells), use the following statement (in IE5+/NN6+ syntax):

```
document.getElementById("myTable").border = 0
```

## borderColor

## borderColorDark

## borderColorLight

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

**Example**

Assuming that you have set the initial light and dark color attributes of a table, the following function swaps the light and dark colors to shift the light source to the opposite corner:

```
function swapColors(tableRef) {
 var oldLight = tableRef.borderColorLight
 tableRef.borderColorLight = tableRef.borderColorDark
 tableRef.borderColorDark = oldLight
}
```

While you can easily invoke this function over and over by ending it with a `setTimeout()` method that calls this function after a fraction of a second, the results are very distracting to the person trying to read your page. Please don't do it.

## caption

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

The following example, for use with The Evaluator (Chapter 13) in NN6+, demonstrates the sequence of assigning a new CAPTION element object to a table. While the table in The Evaluator already has a CAPTION element, the following statements replace it with an entirely new one. Enter each of the following statements into the top text box, starting with the one that saves a long reference into a variable for multiple use at the end:

```
t = document.getElementById("myTable")
a = document.createElement("CAPTION")
b = document.createTextNode("A Brand New Caption")
a.appendChild(b)
t.replaceChild(a, t.caption)
```

A view of the table shows that the new caption has replaced the old one because a table can have only one CAPTION element.

cellPadding  
cellSpacing

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

**Example**

Use The Evaluator (Chapter 13) to adjust the cellPadding and cellSpacing properties of the demonstrator table. First, adjust the padding (IE5+/NN6 syntax):

```
document.getElementById("myTable").cellPadding = 50
```

Now, adjust the cell spacing:

```
document.getElementById("myTable").cellSpacing = 15
```

Notice how cellSpacing affected the thickness of inter-cell borders.

## cells

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

Use The Evaluator with IE5+ for Windows to have JavaScript calculate the number of columns in the demonstrator table with the help of the `cells` and `rows` properties. Enter the following statement into the top text box:

```
document.all.myTable.cells.length/document.all.myTable.rows.length
```

The result is the number of columns in the table.

## dataPageSize

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

If you want to change the number of visible rows of linked data in the table to 15, use the following statement:

```
document.all.myTable.dataPageSize = 15
```

## frame

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Listing 27-4 presents a page that cycles through all possible settings for the `frame` property. The `frame` property value is displayed in the table's caption. (Early versions of NN6 might fail to refresh part of the page after adjusting the `frame` property.)

**Listing 27-4: Cycling Through Table frame Property Values**

```

<HTML>
<HEAD>
<TITLE>TABLE.frame Property</TITLE>

<SCRIPT LANGUAGE="JavaScript">
var timeoutID
var frameValues = ["box", "above", "rhs", "below", "lhs", "hsides", "vsides",
 "border", "void"]
function rotateBorder(i) {
 document.getElementById("myTABLE").frame = frameValues[i]
 document.getElementById("myCAPTION").innerHTML = frameValues[i]
 i = (++i == frameValues.length) ? 0 : i
 timeoutID = setTimeout("rotateBorder(" + i + ")", 2000)
}
function stopRotate() {
 clearTimeout(timeoutID)
 document.getElementById("myTABLE").frame = "box"
 document.getElementById("myCAPTION").innerHTML = "box"
}
</SCRIPT>
</HEAD>

<BODY>
<H1>TABLE.frame Property</H1>
<HR>
<FORM NAME="controls">
<FIELDSET>
<LEGEND>Cycle Table Edge Visibility</LEGEND>
<TABLE WIDTH="100%" CELLSPACING=20><TR>
<TD><INPUT TYPE="button" VALUE="Cycle" onClick="rotateBorder(0)"></TD>
<TD><INPUT TYPE="button" VALUE="Stop" onClick="stopRotate()"></TD>
</TR>
</TABLE>
</FIELDSET>
</TABLE>
</FIELDSET>
</FORM>
<HR>
<TABLE ID="myTABLE" CELLPADDING=5 BORDER=3 ALIGN="center">
<CAPTION ID="myCAPTION">Default</CAPTION>
<THEAD ID="myTHEAD">
<TR>
<TH>River<TH>Outflow<TH>Miles<TH>Kilometers
</TR>

```

*Continued*

## Listing 27-4 (continued)

```

</THEAD>
<TBODY>
<TR>
 <TD>Nile<TD>Mediterranean<TD>4160<TD>6700
</TR>
<TR>
 <TD>Congo<TD>Atlantic Ocean<TD>2900<TD>4670
</TR>
<TR>
 <TD>Niger<TD>Atlantic Ocean<TD>2600<TD>4180
</TR>
<TR>
 <TD>Zambezi<TD>Indian Ocean<TD>1700<TD>2740
</TR>
</TABLE>
</BODY>
</HTML>

```

## height width

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to adjust the width of the demonstrator table. Begin by increasing the width to the full width of the page:

```
document.getElementById("myTable").width = "100%"
```

To restore the table to its minimum width, assign a very small value to the property:

```
document.getElementById("myTable").width = 50
```

If you have IE4+, you can perform similar experiments with the `height` property of the table.

## rows

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator to examine the number of rows in the demonstrator table. Enter the following statement into the top text box:

```
document.getElementById("myTable").rows.length
```

In contrast, notice how the `rows` property sees only the rows within the demonstrator table's `TBODY` element:

```
document.getElementById("myTbody").rows.length
```

## rules

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Listing 27-5 presents a page that cycles through all possible settings for the `rows` property. The `rows` property value is displayed in the table's caption. When you run this script, notice the nice border display for this table's combination of `COLGROUP` and table row segment elements. Early versions of NN6 may not render the altered table correctly, and scripted changes won't appear on the page.

**Listing 27-5: Cycling Through Table `rows` Property Values**

```
<HTML>
<HEAD>
<TITLE>TABLE.rules Property</TITLE>
```

*Continued*

## Listing 27-5 (continued)

```

<SCRIPT LANGUAGE="JavaScript">
var timeoutID
var rulesValues = ["all", "cols", "groups", "none", "rows"]
function rotateBorder(i) {
 document.getElementById("myTABLE").rules = rulesValues[i]
 document.getElementById("myCAPTION").innerHTML = rulesValues[i]
 i = (++i == rulesValues.length) ? 0 : i
 timeoutID = setTimeout("rotateBorder(" + i + ")", 2000)
}
function stopRotate() {
 clearTimeout(timeoutID)
 document.getElementById("myTABLE").rules = "all"
 document.getElementById("myCAPTION").innerHTML = "all"
}
</SCRIPT>
</HEAD>

<BODY>
<H1>TABLE.rules Property</H1>
<HR>
<FORM NAME="controls">
<FIELDSET>
<LEGEND>Cycle Table Rule Visibility</LEGEND>
<TABLE WIDTH="100%" CELLSPACING=20><TR>
<TD><INPUT TYPE="button" VALUE="Cycle" onClick="rotateBorder(0)"></TD>
<TD><INPUT TYPE="button" VALUE="Stop" onClick="stopRotate()"></TD>
</TR>
</TABLE>
</FIELDSET>
</TABLE>
</FIELDSET>
</FORM>
<HR>
<TABLE ID="myTABLE" CELLPADDING=5 BORDER=3 ALIGN="center">
<CAPTION ID="myCAPTION">Default</CAPTION>
<COLGROUP SPAN=1>
<COLGROUP SPAN=3>
<THEAD ID="myTHEAD">
<TR>
 <TH>River<TH>Outflow<TH>Miles<TH>Kilometers
</TR>
</THEAD>
<TBODY>
<TR>
 <TD>Nile<TD>Mediterranean<TD>4160<TD>6700
</TR>
<TR>
 <TD>Congo<TD>Atlantic Ocean<TD>2900<TD>4670

```

```

</TR>
<TR>
 <TD>Niger<TD>Atlantic Ocean<TD>2600<TD>4180
</TR>
<TR>
 <TD>Zambezi<TD>Indian Ocean<TD>1700<TD>2740
</TR>
</TABLE>
</BODY>
</HTML>

```

## tBodies

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to access the `tBodies` array and reveal the number of rows in the one `TBODY` segment of the demonstrator table. Enter the following statement into the top text box:

```
document.getElementById("myTable").tBodies[0].rows.length
```

## Methods

`moveRow(sourceRowIndex, destinationRowIndex)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>								✓	✓

### Example

If you want to shift the bottom row of a table to the top, you can use the shortcut reference to the last item's index value (-1) for the first parameter:

```
var movedRow = document.all.someTable.moveRow(-1, 0)
```

## TBODY, TFOOT, and THEAD Element Objects

### Properties

vAlign

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to modify the vertical alignment of the content of the TBODY element in the demonstrator table. Enter the following statement in the top text box to shift the content to the bottom of the cells:

```
document.getElementById("myTBody").vAlign = "bottom"
```

Notice that the cells of the THEAD element are untouched by the action imposed on the TBODY element.

## COL and COLGROUP Element Objects

### Properties

span

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

### Example

The following statement assigns a span of 3 to a newly created COLGROUP element stored in the variable colGroupA:

```
colGroupA.span = 3
```

# TR Element Object

## Properties

### cells

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to retrieve the number of TD elements in the second row of the demonstrator table. Enter the following statement into the top text box (W3C DOM syntax shown here):

```
document.getElementById("myTable").rows[1].cells.length
```

### height

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) in IE4+ to expand the height of the second row of the demonstrator table. Enter the following statement into the top text box:

```
document.all.myTable.rows[1].height = 300
```

If you attempt to set the value very low, the rendered height goes no smaller than the default height.

## rowIndex sectionRowIndex

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to explore the `rowIndex` and `sectionRowIndex` property values for the second physical row in the demonstrator table. Enter each of the following statements into the top text box (W3C DOM syntax shown here):

```
document.getElementById("myTable").rows[1].rowIndex
document.getElementById("myTable").rows[1].sectionRowIndex
```

The result of the first statement is 1 because the second row is the second row of the entire table. But the `sectionRowIndex` property returns 0 because this row is the first row of the `TBODY` element in this particular table.

## TD and TH Element Objects

### Properties

#### cellIndex

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

You can rewrite the cell addition portion of Listing 27-2 to utilize the `cellIndex` property. The process entails modifying the `insertTableRow()` function so that it uses a `do...while` construction to keep adding cells to match the number of data slots. The function looks like the following (changes shown in boldface):

```
function insertTableRow(form, where) {
 var now = new Date()
 var nowData = [now.getHours(), now.getMinutes(), now.getSeconds(),
 now.getMilliseconds()]
 clearBGColors()
 var newCell
 var newRow = theTableBody.insertRow(where)
 var i = 0
 do {
 newCell = newRow.insertCell(i)
 newCell.innerHTML = nowData[i++]
 newCell.style.backgroundColor = "salmon"
 } while (newCell.cellIndex < nowData.length)
 updateRowCounters(form)
}
```

This version is merely for demonstration purposes and is not as efficient as the sequence shown in Listing 27-2. But the `cellIndex` property version can give you some implementation ideas for the `property`. It also shows how dynamic the property is, even for brand new cells.

## colSpan rowSpan

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to witness how modifying either of these properties in an existing table can destroy the table. Enter the following statement into the top text box:

```
document.getElementById("myTable").rows[1].cells[0].colSpan = 3
```

Now that the first cell of the second row occupies the space of three columns, the browser has no choice but to shift the two other defined cells for that row out beyond the original boundary of the table. Experiment with the `rowSpan` property the same way. To restore the original settings, assign 1 to each property.

## height width

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see the results of setting the `height` and `width` properties of an existing table cell. Enter each of the following statements into the top text box and study the results in the demonstrator table (W3C DOM syntax used here):

```
document.getElementById("myTable").rows[1].cell[1].height = 100
document.getElementById("myTable").rows[2].cell[0].width = 300
```

You can restore both cells to their original sizes by assigning very small values, such as 1 or 0, to the properties. The browser prevents the cells from rendering any smaller than is necessary to show the content.

## noWrap

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The following statement creates a new cell in a row and sets its `noWrap` property to prevent text from word-wrapping inside the cell:

```
newCell = newRow.insertCell(-1)
newCell.noWrap = true
```

You need to set this property only if the cell must behave differently than the default, word-wrapping style.

# OL Element Object

## Properties

start

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The following statements generate a new OL element and assign a value to the `start` property:

```
var newOL = document.createElement("OL")
newOL.start = 5
```

type

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

The following statements generate a new OL element and assign a value to the `type` property so that the sequence letters are uppercase Roman numerals:

```
var newOL = document.createElement("OL")
newOL.type = "I"
```

# UL Element Object

## Properties

type

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

### Example

The following statements generate a new UL element and assign a value to the `type` property so that the bullet characters are empty circles:

```
var newUL = document.createElement("UL")
newUL.type = "circle"
```

# LI Element Object

## Properties

type

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

### Example

See the examples for the `OL.type` and `UL.type` properties earlier in this chapter.

value

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓			✓	✓	✓

**Example**

The following statements generate a new LI element and assign a value to the `start` property:

```
var newLI = document.createElement("LI")
newLI.start = 5
```

## Chapter 28 Examples

The following sections contain examples from Chapter 28, “The Navigator and Other Environment Objects.”

### clientInformation Object (IE4+) and navigator Object (All)

**Properties**

appCodeName  
appName  
appVersion  
userAgent

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

**Example**

Listing 28-1 provides a number of reusable functions that your scripts can employ to determine a variety of information about the currently running browser. This is not intended in any way to be an all-inclusive browser-sniffing routine; instead, I offer samples of how to extract information from the key navigator properties to determine various browser conditions.

All functions in Listing 28-1 return a Boolean value inline with the pseudo-question presented in the function’s name. For example, the `isWindows()` function returns `true` if the browser is any type of Windows browser; otherwise, it returns `false`. (In Internet Explorer 3, the values are 0 for `false` and -1 for `true`, but those values

are perfectly usable in `if` conditional phrases). If this kind of browser detection occurs frequently in your pages, consider moving these functions into an external `.js` source library for inclusion in your pages (see Chapter 13).

When you load this page, it presents fields that display the results of each function depending on the type of browser and client operating system you use.

### Listing 28-1: Functions to Examine Browsers

```
<HTML>
<HEAD>
<TITLE>UserAgent Property Library</TITLE>
<SCRIPT LANGUAGE="JavaScript">
// basic brand determination
function isNav() {
 return (navigator.appName == "Netscape")
}

function isIE() {
 return (navigator.appName == "Microsoft Internet Explorer")
}

// operating system platforms
function isWindows() {
 return (navigator.appVersion.indexOf("Win") != -1)
}

function isWin95NT() {
 return (isWindows() && (navigator.appVersion.indexOf("Win16") == -1 &&
 navigator.appVersion.indexOf("Windows 3.1") == -1))
}

function isMac() {
 return (navigator.appVersion.indexOf("Mac") != -1)
}

function isMacPPC() {
 return (isMac() && (navigator.appVersion.indexOf("PPC") != -1 ||
 navigator.appVersion.indexOf("PowerPC") != -1))
}

function isUnix() {
 return (navigator.appVersion.indexOf("X11") != -1)
}

// browser versions
function isGeneration2() {
 return (parseInt(navigator.appVersion) == 2)
}
```

```

function isGeneration3() {
 return (parseInt(navigator.appVersion) == 3)
}

function isGeneration3Min() {
 return (parseInt(navigator.appVersion.charAt(0)) >= 3)
}

function isNav4_7() {
 return (isNav() && parseFloat(navigator.appVersion) == 4.7)
}

function isMSIE4Min() {
 return (isIE() && navigator.appVersion.indexOf("MSIE") != -1)
}

function isMSIE5_5() {
 return (navigator.appVersion.indexOf("MSIE 5.5") != -1)
}

function isNN6Min() {
 return (isNav() && parseInt(navigator.appVersion) >= 5)
}

// element referencing syntax
function isDocAll() {
 return (document.all) ? true : false
}

function isDocW3C() {
 return (document.getElementById) ? true : false
}

// fill in the blanks
function checkBrowser() {
 var form = document.forms[0]
 form.brandNN.value = isNav()
 form.brandIE.value = isIE()
 form.win.value = isWindows()
 form.win32.value = isWin95NT()
 form.mac.value = isMac()
 form.ppc.value = isMacPPC()
 form.unix.value = isUnix()
 form.ver30only.value = isGeneration3()
 form.ver3Up.value = isGeneration3Min()
 form.Nav4_7.value = isNav4_7()
 form.Nav6Up.value = isNN6Min()
 form.MSIE4.value = isMSIE4Min()
 form.MSIE5_5.value = isMSIE5_5()
 form.doc_all.value = isDocAll()
}

```

*Continued*

## Listing 28-1 (continued)

```

 form.doc_w3c.value = isDocW3C()
 }
</SCRIPT>
</HEAD>

<BODY onLoad="checkBrowser()">
<H1>About This Browser</H1>
<FORM>
<H2>Brand</H2>
Netscape Navigator:<INPUT TYPE="text" NAME="brandNN" SIZE=5>

</FORM>
</BODY>
</HTML>

```

Sometimes you may need to use more than one of these functions together. For example, if you want to create a special situation for the `window.open()` bug that afflicts UNIX and Macintosh versions of Navigator 2, then you have to put your Boolean operator logic powers to work to construct a fuller examination of the browser:

```

function isWindowBuggy() {
 return (isGeneration2() && (isMac() || isUnix()))
}

```

You can see many more examples of browser sniffing, including more details about handling AOL browsers, in an article by Eric Krock at: [http://developer.netscape.com:80/docs/examples/javascript/browser\\_type.html](http://developer.netscape.com:80/docs/examples/javascript/browser_type.html).

## appMinorVersion

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to examine the two related version properties of your IE browser(s). Type the following two statements into the top text box and observe the results:

```
navigator.appVersion
navigator.minorAppVersion
```

There is a good chance that the values returned are not related to the browser version number shown after MSIE in the `appVersion` value.

## cookieEnabled

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator to see the value of the `navigator.cookieEnabled` property on your browsers. Enter the following statement into the top text box:

```
navigator.cookieEnabled
```

Feel free to change the cookie preferences setting temporarily to see the new value of the property. You do not have to relaunch the browser for the new setting to take effect.

## cpuClass

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see how IE reports the `cpuClass` of your PC. Enter the following statement into the top text box:

```
navigator.cpuClass
```

## mimeTypes

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			(✓)	(✓)	(✓)

### Example

For examples of the `mimeTypes` property and details about using the `mimeType` object, see the discussion of this object later in the chapter. A number of simple examples showing how to use this property to see whether the `navigator` object has a particular MIME type do not go far enough in determining whether a plug-in is installed and enabled to play the incoming data.

## onLine

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see the online state of your IE browsers. Enter the following statement into the top text box:

```
navigator.onLine
```

Verify your browsing mode by checking the Work Offline choice in the File menu. If it is checked, the `onLine` property should return `false`.

## oscpu

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) with NN6 to see what your client machine reports to you by entering the following statement into the top text box:

```
navigator.oscpu
```

## platform

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see what your computer reports as its operating system. Enter the following statement into the top text box:

```
navigator.platform
```

## product productSub vendor vendorSub

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) on your copy of NN6 to see the values returned for these four properties. Enter each of the following statements into the top text box of the page and see the values for each in the Results box:

```
navigator.product
navigator.productSub
navigator.vendor
navigator.vendorSub
```

Also check the value of the `navigator.userAgent` property to see how many of these four property values are revealed in the `userAgent` property.

## systemLanguage userLanguage

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) with your IE4+ browser to compare the values of the three language-related properties running on your computer. Enter each of the following statements into the top text box:

```
navigator.browserLanguage
navigator.systemLanguage
navigator.userLanguage
```

Don't be surprised if all three properties return the same value.

## Methods

### preference(*name* [, *val*])

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓					

## Example

The page in Listing 28-2 displays checkboxes for several preference settings plus one text box to show a preference setting value for the size of the browser's disk cache. To run this script without signing the scripts, turn on codebase principals as directed in Chapter 46. (The listing file on the CD-ROM does not employ signed scripts.)

One function reads all the preferences and sets the form control values accordingly. Another function sets a preference when you click its checkbox. Because of the interaction among three of the cookie settings, it is easier to have the script rerun the `showPreferences()` function after each setting rather than you trying to manually control the properties of the three checkboxes. Rerunning that function also helps verify that you set the preference.

### Listing 28-2: Reading and Writing Browser Preferences

```
<HTML>
<HEAD>
<TITLE>Reading/Writing Browser Preferences</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
function setPreference(pref, value) {
 netscape.security.PrivilegeManager.enablePrivilege(
 "UniversalPreferencesWrite")
 navigator.preference(pref, value)
 netscape.security.PrivilegeManager.revertPrivilege(
 "UniversalPreferencesWrite")
 showPreferences()
}

function showPreferences() {
 var form = document.forms[0]
 netscape.security.PrivilegeManager.enablePrivilege(
 "UniversalPreferencesRead")
 form.imgLoad.checked = navigator.preference("general.always_load_images")
 form.cacheSize.value = navigator.preference("browser.cache.disk_cache_size")
 form.ssEnable.checked = navigator.preference("browser.enable_style_sheets")
 form.autoIEnable.checked = navigator.preference("autoupdate.enabled")
 var cookieSetting = navigator.preference("network.cookie.cookieBehavior")
 for (var i = 0; i < 3; i++) {
 form.elements["cookie" + i].checked = (i == cookieSetting) ? true :
false
 }
}
```

*Continued*

## Listing 28-2 (continued)

```

 form.cookieWarn.checked =
navigator.preference("network.cookie.warnAboutCookies")
 netscape.security.PrivilegeManager.revertPrivilege(
 "UniversalPreferencesRead")
}
</SCRIPT>
</HEAD>

<BODY onLoad="showPreferences()">
<H1>Browser Preferences Settings Sampler</H1>
<HR>
<FORM>
<INPUT TYPE="checkbox" NAME="imgLoad"
onClick="setPreference('general.always_load_images',this.checked)">
Automatically Load Images

<INPUT TYPE="checkbox" NAME="ssEnable"
onClick="setPreference('browser.enable_style_sheets',this.checked)">
Style Sheets Enabled

<INPUT TYPE="checkbox" NAME="autoIEnable"
onClick="setPreference('autoupdate.enabled',this.checked)">
AutoInstall Enabled

<INPUT TYPE="checkbox" NAME="cookie0"
onClick="setPreference('network.cookie.cookieBehavior',0)">
Accept All Cookies

<INPUT TYPE="checkbox" NAME="cookie1"
onClick="setPreference('network.cookie.cookieBehavior',1)">
Accept Only Cookies Sent Back to Server

<INPUT TYPE="checkbox" NAME="cookie2"
onClick="setPreference('network.cookie.cookieBehavior',2)">
Disable Cookies

<INPUT TYPE="checkbox" NAME="cookieWarn"
onClick="setPreference('network.cookie.warnAboutCookies',this.checked)">
Warn Before Accepting Cookies

Disk cache is <INPUT TYPE="text" NAME="cacheSize" SIZE=10> KB

</FORM>
</BODY>
</HTML>

```

# screen Object

## Properties

`availLeft`  
`availTop`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓					

## Example

If you are a Windows user, you can experiment with these NN4+ properties via The Evaluator (Chapter 13). With the taskbar at the bottom of the screen, enter these two statements into the top text box:

```
screen.availLeft
screen.availTop
```

Next, drag the taskbar to the top of the screen and try both statements again. Now, drag the taskbar to the left edge of the screen and try the statements once more.

# userProfile Object

## Methods

`addReadRequest("attributeName")`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 28-4 for an example of the `addReadRequest()` method in action. You can also invoke it from the top text box in The Evaluator. For example, enter the following statement to queue one request:

```
navigator.userProfile.addReadRequest("vCard.LastName")
```

To continue the process, see examples for `doReadRequest()` and `getAttribute()` later in this chapter.

```
doReadRequest(reasonCode, identification[,
domain[, path[, expiration]]])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 28-4 for an example of the `doReadRequest()` method in action. If you entered the `addReadRequest()` example for The Evaluator earlier in this chapter, you can now bring up the permissions dialog box (if you have a user profile for your version of Windows) by entering the following statement into the top text box:

```
navigator.userProfile.doReadRequest(1, "Just me!")
```

```
getAttribute("attributeName")
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

See Listing 28-4 for an example of the `getAttribute()` method in action. Also, if you followed The Evaluator examples for this object, you can now extract the desired information (provided it is in your user profile). Enter the following statement into the top text box:

```
navigator.userProfile.getAttribute("vCard.LastName")
```

## Chapter 29 Examples

The following sections contain examples from Chapter 29, “Event Objects.”

### NN4 event Object

#### Properties

data

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

#### Example

The page in Listing 29-12 contains little more than a TEXTAREA in which the URLs of dragged items are listed. To run this script without signing the scripts, turn on codebase principals, as directed in Chapter 46.

To experiment with this listing, load the page and drag any desktop icons that represent files, applications, or folders to the window. Select multiple items and drag them all at once. Because the `onDragDrop` event handler evaluates to `return false`, the files are not loaded into the window. If you want merely to look at the URL and allow only some to process, you would generate an `if...else` construction to return `true` or `false` to the event handler as needed. A value of `return true` allows the normal processing of the `DragDrop` event to take place after your event handler function has completed its processing.

#### Listing 29-12: Obtaining URLs of a DragDrop Event’s data Property

```
<HTML>
<HEAD>
<TITLE>Drag and Drop</TITLE>
<SCRIPT LANGUAGE="JavaScript1.2">
function handleDrag(evt) {
 netscape.security.PrivilegeManager.enablePrivilege("UniversalBrowserRead")
```

*Continued*

**Listing 29-12 (continued)**

```

var URLArray = evt.data
netscape.security.PrivilegeManager.disablePrivilege("UniversalBrowserRead")
if (URLArray) {
 document.forms[0].output.value = URLArray.join("\n")
} else {
 document.forms[0].output.value = "Nothing found."
}
return false
}
</SCRIPT>
</HEAD>
<BODY onDragDrop="return handleDrag(event)">
Drag a URL to this window (NN4 only).
<HR>
<FORM>
URLs:

<TEXTAREA NAME="output" COLS=70 ROWS=4></TEXTAREA>

<INPUT TYPE="reset">
</FORM>
</BODY>
</HTML>

```

layerX  
layerY  
pageX  
pageY  
screenX  
screenY

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

**Example**

You can see the effects of the coordinate systems and associated properties with the page in Listing 29-13. Part of the page contains a three-field readout of the layer-, page-, and screen-level properties. Two clickable objects are provided so that you can see the differences between an object not in any layer and an object residing

within a layer. The object not confined by a layer has its layer and page coordinates the same in the event object properties.

Additional readouts display the event object coordinates for resizing and moving a window. If you maximize the window under Windows, the Navigator browser's top-left corner is actually out of sight, four pixels up and to the left. That's why the screenX and screenY values are both -4.

### Listing 29-13: NN4 Event Coordinate Properties

```
<HTML>
<HEAD>
<TITLE>X and Y Event Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function checkCoords(evt) {
 var form = document.forms[0]
 form.layerCoords.value = evt.layerX + "," + evt.layerY
 form.pageCoords.value = evt.pageX + "," + evt.pageY
 form.screenCoords.value = evt.screenX + "," + evt.screenY
 return false
}
function checkSize(evt) {
 document.forms[0].resizeCoords.value = evt.layerX + "," + evt.layerY
}
function checkLoc(evt) {
 document.forms[0].moveCoords.value = evt.screenX + "," + evt.screenY
}
</SCRIPT>
</HEAD>
<BODY onResize="checkSize(event)" onMove="checkLoc(event)">

# IE4+ event Object

## Properties

- clientX
- clientY
- offsetX
- offsetY
- screenX
- screenY
- x
- y

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

## Example

Listing 29-14 provides readings of all event coordinate properties in an interactive way. An `onMouseDown` event handler triggers all event handling, and you can click the mouse anywhere on the page to see what happens. You see the tag of the element targeted by the mouse event to help you visualize how some of the coordinate properties are determined. An image is encased inside a positioned DIV element to help you see what happens to some of the properties when the event is targeted inside a positioned element.

### Listing 29-14: IE4+ Event Coordinate Properties

```
<HTML>
<HEAD>
<TITLE>X and Y Event Properties (IE4+)</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function checkCoords() {
 var form = document.forms[0]
 form.srcElemTag.value = "<" + event.srcElement.tagName + ">"
 form.clientCoords.value = event.clientX + "," + event.clientY
 form.pageCoords.value = (event.clientX + document.body.scrollLeft) +
 "," + (event.clientY + document.body.scrollTop)
 form.offsetCoords.value = event.offsetX + "," + event.offsetY
 form.screenCoords.value = event.screenX + "," + event.screenY
 form.xyCoords.value = event.x + "," + event.y
 form.parElem.value = "<" + event.srcElement.offsetParent.tagName + ">"
 return false
}
function handleSize() {
 document.forms[0].resizeCoords.value = event.clientX + "," + event.clientY
}
</SCRIPT>
</HEAD>
<BODY onMouseDown="checkCoords()" onResize="handleSize()">

<DIV ID="display" STYLE="position:relative; left:100">

</DIV>
</BODY>
</HTML>

```

Here are some tasks to try with the page that loads from Listing 29-14 to help you understand the relationships among the various pairs of coordinate properties:

1. Click the dot above the “i” on the “Click Here” button label. The target element is the button (INPUT) element, whose `offsetParent` is a table cell element. The `offsetY` value is very low because you are near the top of the element’s own coordinate space. The client coordinates (and `x` and `y`), however, are relative to the viewable area in the window. If your browser window is maximized in Windows, the `screenX` and `clientX` values will be the same; the difference between `screenY` and `clientY` is the height of all the window chrome above the content region. With the window not scrolled at all, the client coordinates are the same with and without scrolling taken into account.
2. Jot down the various coordinate values and then scroll the page down slightly (clicking the scrollbar fires an event) and click the dot on the button again. The `clientY` value shrinks because the page has moved upward relative to the viewable area, making the measure between the top of the area smaller with respect to the button. The Windows version does the right thing with the offset properties, by continuing to return values relative to the element’s own coordinate space; the Mac, unfortunately, subtracts the scrolled amount from the offset properties.

3. Click the large image. The client properties perform as expected for both Windows and Mac, as do the screen properties. For Windows, the `x` and `y` properties correctly return the event coordinates relative to the `IMG` element's `offsetParent`, which is the `DIV` element that surrounds it. Note, however, that the browser “sees” the `DIV` as starting 10 pixels to the left of the image. In IE5.5/Windows, you can click within those ten transparent pixels to the left of the image to click the `DIV` element. This padding is inserted automatically and impacts the coordinates of the `x` and `y` properties. A more reliable measure of the event inside the image is the `offset` properties. The same is true in the Macintosh version, as long as the page isn't scrolled, in which case the scroll, just as in Step 2, affects the values above.
4. Click the top `HR` element under the heading. It may take a couple of tries to actually hit the element (you've made it when the `HR` element shows up in the `srcElement` box). This is to reinforce the way the client properties provide coordinates within the element itself (again, accept on the Mac when the page is scrolled). Clicking at the very left end of the rule, you eventually find the 0,0 coordinate.

Finally, if you are a Windows user, here are two examples to try to see some of the unexpected behavior of coordinate properties.

1. With the page not scrolled, click anywhere along the right side of the page, away from any text so that the `BODY` element is `srcElement`. Because the `BODY` element theoretically fills the entire content region of the browser window, all coordinate pairs except for the screen coordinates should be the same. But `offset` properties are two pixels less than all the others. By and large, this difference won't matter in your scripts, but you should be aware of this potential discrepancy if precise positioning is important. For inexplicable reasons, the `offset` properties are measured in a space that is inset two pixels from the left and top of the window. This is not the case in the Macintosh version, where all value pairs are the same from the `BODY` perspective.
2. Click the text of the `H1` or `P` elements (just above and below the long horizontal rule at the top of the page). In theory, the `offset` properties should be relative to the rectangles occupied by these elements (they're block elements, after all). But instead, they're measured in the same space as the client properties (plus the two pixels). This unexpected behavior doesn't have anything to do with the cursor being a text cursor, because if you click inside any of the text box elements, their `offset` properties are properly relative to their own rectangles. This problem does not afflict the Macintosh version.

You can see further examples of key event coordinate properties in action in Chapter 31's example of dragging elements around the page.

## fromElement toElement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 29-15 provides an example of how the `fromElement` and `toElement` properties can reveal the life of the cursor action before and after it rolls into an element. When you roll the cursor to the center box (a table cell), its `onMouseOver` event handler displays the text from the table cell from which the cursor arrived. If the cursor comes in from one of the corners (not easy to do), a different message is displayed.

### Listing 29-15: Using the `toElement` and `fromElement` Properties

```
<HTML>
<HEAD>
<TITLE>fromElement and toElement Properties</TITLE>
<STYLE TYPE="text/CSS">
.direction {background-color:#00FFFF; width:100; height:50; text-align:center}
#main {background-color:#FF6666; text-align:center}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function showArrival() {
 var direction = (event.fromElement.innerText) ? event.fromElement.innerText :
 "parts unknown"
 status = "Arrived from: " + direction
}
function showDeparture() {
 var direction = (event.toElement.innerText) ? event.toElement.innerText :
 "parts unknown"
 status = "Departed to: " + direction
}
</SCRIPT>
</HEAD>
<BODY>
<H1>fromElement and toElement Properties</H1>
<HR>
<P>Roll the mouse to the center box and look for arrival information
```

in the status bar. Roll the mouse away from the center box and look for departure information in the status bar.</P>

```
<TABLE CELLSPACING=0 CELLPADDING=5>
<TR><TD></TD><TD CLASS="direction">North</TD><TD></TD></TR>
<TR><TD CLASS="direction">West</TD>
<TD ID="main" onMouseOver="showArrival()" onMouseOut="showDeparture()">Roll</TD>
<TD CLASS="direction">East</TD></TR>
<TR><TD></TD><TD CLASS="direction">South</TD><TD></TD></TR>
</TABLE>
</BODY>
</HTML>
```

This is a good example to experiment with in the browser, because it also reveals a potential limitation. The element registered as the `toElement` or `fromElement` must fire a mouse event to register itself with the browser. If not, the next element in the sequence that registers itself is the one acknowledged by these properties. For example, if you roll the mouse into the center box and then extremely quickly roll the cursor to the bottom of the page, you may bypass the South box entirely. The text that appears in the statusbar is actually the inner text of the BODY element, which is the element that caught the first mouse event to register itself as the `toElement` for the center table cell.

## keyCode

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Listing 29-16 provides an additional play area to view the `keyCode` property for all three keyboard events while you type into a TEXTAREA. You can use this page later as an authoring tool to grab the precise codes for keyboard keys you may not be familiar with.

#### Listing 29-16: Displaying keyCode Property Values

```
<HTML>
<HEAD>
<TITLE>keyCode Property</TITLE>
```

*Continued*

(IE) `event.keyCode`

## Listing 29-16 (continued)

```

<STYLE TYPE="text/css">
TD {text-align:center}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function showCode(which) {
 document.forms[0].elements[which].value = event.keyCode
}
function clearEm() {
 for (var i = 1; i < document.forms[0].elements.length; i++) {
 document.forms[0].elements[i].value = ""
 }
}
</SCRIPT>
</HEAD>
<BODY>
<H1>keyCode Property</H1>
<HR>
<P></P>
<FORM>
<P>
<TEXTAREA NAME="scratchpad" COLS="40" ROWS="5" WRAP="hard"
onKeyDown="clearEm(); showCode('down')" onKeyUp="showCode('up')"
onKeyPress="showCode('press')"></TEXTAREA>
</P>
<TABLE CELLSPACING="5">
<TR><TH>Event</TH><TH>event.keyCode</TH></TR>
<TR><TD>onKeyDown:</TD><TD><INPUT TYPE="text" NAME="down" SIZE="3"></TD></TR>
<TR><TD>onKeyPress:</TD><TD><INPUT TYPE="text" NAME="press" SIZE="3"></TD></TR>
<TR><TD>onKeyUp:</TD><TD><INPUT TYPE="text" NAME="up" SIZE="3"></TD></TR>
</TABLE>
</FORM>
</BODY>
</HTML>

```

The following are some specific tasks to try with the page to examine key codes (if you are not using a browser set for English and a Latin-based keyboard, your results may vary):

1. Enter a lowercase letter “a”. Notice how the `onKeyPress` event handler shows the code to be 97, which is the Unicode (and ASCII) value for the first of the lowercase letters of the Latin alphabet. But the other two events record just the key’s code: 65.
2. Type an uppercase “A” via the Shift key. If you watch closely, you see that the Shift key, itself, generates the code 16 for the `onKeyDown` and `onKeyUp` events.

But the character key then shows the value 65 for all three events, because the ASCII value of the uppercase letter happens to match the keyboard key code for that letter.

3. Press and release the Down Arrow key (be sure the cursor still flashes in the TEXTAREA, because that's where the keyboard events are being monitored). As a non-character key, it does not fire an `onKeyPress` event. But it does fire the other events, and assigns 40 as the code for this key.
4. Poke around with other non-character keys. Some may produce dialog boxes or menus, but their key codes are recorded nonetheless. Note that not all keys on a Macintosh keyboard register with IE/Mac.

## returnValue

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

You can find several examples of the `returnValue` property at work in Chapter 15. Look at Listings 15-30, 33, 36, 37, 38, and 45. Moreover, many of the other examples in that chapter can substitute the `returnValue` property way of cancelling the default action if the scripts were to be run exclusively on IE4+.

## srcElement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

As a simplified demonstration of the power of the `srcElement` property, Listing 29-17 has but two event handlers defined for the BODY element, each invoking a single function. The idea is that the `onMouseDown` and `onMouseUp` events will bubble up from whatever their targets are, and the event handler functions will find out which element is the target and modify the color style of that element.

An extra flair is added to the script in that each function also checks the `className` property of the target element. If the `className` is `bold` — a class name shared by

three SPAN elements in the paragraph—the style sheet rule for that class is modified so that all items share the same color. Your scripts can do even more in the way of filtering objects that arrive at the functions to perform special operations on certain objects or groups of objects.

Notice that the scripts don't have to know anything about the objects on the page to address each clicked one individually. That's because the `srcElement` property provides all of the specificity needed for acting on the target element.

### Listing 29-17: Using the `srcElement` property

```
<HTML>
<HEAD>
<TITLE>srcElement Property</TITLE>
<STYLE TYPE="text/css">
.bold {font-weight:bold}
.ital {font-style:italic}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function highlight() {
 var elem = event.srcElement
 if (elem.className == "bold") {
 document.styleSheets[0].rules[0].style.color = "red"
 } else {
 elem.style.color = "#FFCC00"
 }
}
function restore() {
 var elem = event.srcElement
 if (elem.className == "bold") {
 document.styleSheets[0].rules[0].style.color = ""
 } else {
 elem.style.color = ""
 }
}
</SCRIPT>
</HEAD>
<BODY onMouseDown="highlight()" onMouseUp="restore()">
<H1>srcElement Property</H1>
<HR>
<P>One event handler...</P>

Can
Cover
Many
Objects

<P>
```

```

sed do eiusmod tempor incididunt
ut labore et dolore magna aliqua.
Ut enim adminim veniam, quis nostrud
exercitation ullamco laboris nisi ut aliquip ex ea
commodo consequat.
</P>
</BODY>
</HTML>

```

## type

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see values returned by the `type` property. Enter the following object name into the bottom text box and press Enter/Return:

```
event
```

If necessary, scroll the Results box to view the `type` property, which should read `keypress`. Now click the List Properties button. The `type` changes to `click`. The reason for these types is that the `event` object whose properties are being shown here is the event that triggers the function to show the properties. From the text box, an `onKeyPress` event handler triggers that process; from the button, an `onClick` event handler does the job.

## NN6+ event Object

```
charCode
```

```
keyCode
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

## Example

Listing 29-18 provides a play area to view the `charCode` and `keyCode` properties for all three keyboard events while you type into a `TEXTAREA`. You can use this later as an authoring tool to grab the precise codes for keyboard keys you may not be familiar with.

### Listing 29-18: Displaying `charCode` and `keyCode` Property Values

```
<HTML>
<HEAD>
<TITLE>charCode and keyCode Properties</TITLE>
<STYLE TYPE="text/css">

</BODY>
</HTML>
```

Here are some specific tasks to try with the page to examine key codes (if you are not using a browser set for English and a Latin-based keyboard, your results may vary):

1. Enter a lowercase letter “a”. Notice how the `onKeyPress` event handler shows the `charCode` to be 97, which is the Unicode (and ASCII) value for the first of the lowercase letters of the Latin alphabet. But the other two event types record just the key’s code: 65.
2. Type an uppercase “A” via the Shift key. If you watch closely, you see that the Shift key, itself, generates the key code 16 for the `onKeyDown` and `onKeyUp` events. But the character key then shows the value 65 for all three events (until you release the Shift key), because the ASCII value of the uppercase letter happens to match the keyboard key code for that letter.
3. Press and release the Down Arrow key (be sure the cursor still flashes in the `TEXTAREA`, because that’s where the keyboard events are being monitored). As a non-character key, all three events stuff a value into the `keyCode` property, but zero into `charCode`. The `keyCode` value for this key is 40.
4. Poke around with other non-character keys. Some may produce dialog boxes or menus, but their key codes are recorded nonetheless.

```
clientX
clientY
layerX
layerY
pageX
pageY
screenX
screenY
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

## Example

You can see the effects of the coordinate systems and associated NN6 properties with the page in Listing 29-19. You can view coordinate values for all four measuring systems, as well as some calculated value. Two clickable objects are provided so that you can see the differences between an object not in any layer and an object residing within a layer (although anything you see is clickable, including text nodes).

One of the calculated fields applies window scrolling values to the client coordinates. But, as you will see, these calculated values are the same as the more convenient page coordinates. The other calculated field shows the coordinates relative to the rectangular space of the target element. Notice in the code that if the `nodeType` of the target indicates a text node, that node's parent node (an element) is used for the calculation.

### Listing 29-19: NN6 Event Coordinate Properties

```
<HTML>
<HEAD>
<TITLE>X and Y Event Properties (NN6+)</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function checkCoords(evt) {
 var form = document.forms["output"]
 var targText, targElem
 if (evt.target.nodeType == 3) {
 targText = "[textnode] inside <" + evt.target.parentNode.tagName + ">"
 targElem = evt.target.parentNode
 } else {
 targText = "<" + evt.target.tagName + ">"
 targElem = evt.target
 }
 form.srcElemTag.value = targText
 form.clientCoords.value = evt.clientX + "," + evt.clientY
 form.clientScrollCoords.value = (evt.clientX + window.scrollX) +
 "," + (evt.clientY + window.scrollY)
 form.layerCoords.value = evt.layerX + "," + evt.layerY
 form.pageCoords.value = evt.pageX + "," + evt.pageY
 form.inElemCoords.value =
 (evt.pageX - targElem.offsetLeft - document.body.offsetLeft) +
 "," + (evt.pageY - targElem.offsetTop - document.body.offsetTop)
 form.screenCoords.value = evt.screenX + "," + evt.screenY
 return false
}

</HTML>

```

## currentTarget

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Listing 29-20 shows the power of the `currentTarget` property in revealing the element that is processing an event during event propagation. Similar to the code in Listing 29-7, this example is made simpler because it lets the event object's properties do more of the work to reveal the identity of each element that processes the event. Event listeners assigned for various propagation modes are assigned to a variety of nodes in the document. After you click the button, each listener in the propagation chain fires in sequence. The alert dialog shows which node is processing the event. And, as in Listing 29-7, the `eventPhase` property is used to help display the propagation mode in force at the time the event is processed by each node.

Listing 29-20: **currentTarget** and **eventPhase** Properties

```

<HTML>
<HEAD>
<TITLE>currentTarget and eventPhase Properties</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function init() {
 // using old syntax to assign bubble-type event handlers
 document.onclick = processEvent
 document.body.onclick = processEvent
 // turn on click event capture for document and form
 document.addEventListener("click", processEvent, true)
 document.forms[0].addEventListener("click", processEvent, true)
 // set bubble event listener for form
 document.forms[0].addEventListener("click", processEvent, false)
}
function processEvent(evt) {
 var currTargTag, msg
 if (evt.currentTarget.nodeType == 1) {
 currTargTag = "<" + evt.currentTarget.tagName + ">"
 } else {
 currTargTag = evt.currentTarget.nodeName
 }
 msg = "Event is now at the " + currTargTag + " level "
 msg += "(" + getPhase(evt) + ")."
 alert(msg)
}
// reveal event phase of current event object
function getPhase(evt) {
 switch (evt.eventPhase) {
 case 1:
 return "CAPTURING"
 break
 case 2:
 return "AT TARGET"
 break
 case 3:
 return "BUBBLING"
 break
 default:
 return ""
 }
}
</SCRIPT>
</HEAD>
<BODY onLoad="init()">
<H1>currentTarget and eventPhase Properties</H1>
<HR>
<FORM>

```

```

<INPUT TYPE="button" VALUE="A Button" NAME="main1"
 onClick="processEvent(event)">
</FORM>
</BODY>
</HTML>

```

You can also click other places on the page. For example, if you click to the right of the button, you will be clicking the FORM element. Event propagation and processing adjusts accordingly. Similarly, if you click the header text, the only event listeners that see the event are in the document and BODY levels.

## eventPhase

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

See Listing 29-20 earlier in this chapter for an example of how you can use a `switch` construction to branch function processing based on the event phase of the current event object.

## relatedTarget

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Listing 29-21 provides an example of how the `relatedTarget` property can reveal the life of the cursor action before and after it rolls into an element. When you roll the cursor to the center box (a table cell), its `onMouseOver` event handler displays the text from the table cell from which the cursor arrived (the `nodeValue` of the text node inside the table cell). If the cursor comes in from one of the corners (not easy to do), a different message is displayed.

The two functions that report the results employ a bit of filtering to make sure that they process the event object only if the event occurs on an element and if the `relatedTarget` element is anything other than a nested text node of the central table cell element. Because nodes respond to events in NN6, this extra filtering prevents processing whenever the cursor makes the transition from the central TD element to its nested text node.

### Listing 29-21: Using the `relatedTarget` Property

```

<HTML>
<HEAD>
<TITLE>relatedTarget Properties</TITLE>
<STYLE TYPE="text/CSS">
.direction {background-color:#00FFFF; width:100; height:50; text-align:center}
#main {background-color:#FF6666; text-align:center}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function showArrival(evt) {
 if (evt.target.nodeType == 1) {
 if (evt.relatedTarget != evt.target.firstChild) {
 var direction = (evt.relatedTarget.firstChild) ?
 evt.relatedTarget.firstChild.nodeValue : "parts unknown"
 status = "Arrived from: " + direction
 }
 }
}
function showDeparture(evt) {
 if (evt.target.nodeType == 1) {
 if (evt.relatedTarget != evt.target.firstChild) {
 var direction = (evt.relatedTarget.firstChild) ?
 evt.relatedTarget.firstChild.nodeValue : "parts unknown"
 status = "Departed to: " + direction
 }
 }
}
</SCRIPT>
</HEAD>
<BODY>

## target

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

As a simplified demonstration of the power of the `target` property, Listing 29-22 has but two event handlers defined for the `BODY` element, each invoking a single function. The idea is that the `onMouseDown` and `onMouseUp` events will bubble up from whatever their targets are, and the event handler functions will find out which element is the target and modify the color style of that element.

An extra flair is added to the script in that each function also checks the `className` property of the target element. If the `className` is `bold`—a class name shared by three `SPAN` elements in the paragraph—the style sheet rule for that class is modified so that all items share the same color. Your scripts can do even more in the way of filtering objects that arrive at the functions to perform special operations on certain objects or groups of objects.

Notice that the scripts don't have to know anything about the objects on the page to address each clicked one individually. That's because the `target` property provides all of the specificity needed for acting on the target element.

### Listing 29-22: Using the target Property

```

<HTML>
<HEAD>
<TITLE>target Property</TITLE>

```

*Continued*

## Listing 29-22 (continued)

```

<STYLE TYPE="text/css">
.bold {font-weight:bold}
.ital {font-style:italic}
</STYLE>
<SCRIPT LANGUAGE="JavaScript">
function highlight(evt) {
 var elem = (evt.target.nodeType == 3) ? evt.target.parentNode : evt.target
 if (elem.className == "bold") {
 document.styleSheets[0].cssRules[0].style.color = "red"
 } else {
 elem.style.color = "#FFCC00"
 }
}
function restore(evt) {
 var elem = (evt.target.nodeType == 3) ? evt.target.parentNode : evt.target
 if (elem.className == "bold") {
 document.styleSheets[0].cssRules[0].style.color = "black"
 } else {
 elem.style.color = "black"
 }
}

</HTML>

```

## timeStamp

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Listing 29-23 uses the `timeStamp` property to calculate the instantaneous typing speed when you type into a `TEXTAREA`. The calculations are pretty raw, and work only on intra-keystroke times without any averaging or smoothing that a more sophisticated typing tutor might perform. Calculated values are rounded to the nearest integer.

### Listing 29-23: Using the `timeStamp` property

```
<HTML>
<HEAD>
<TITLE>timeStamp Property</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var stamp
function calcSpeed(evt) {
 if (stamp) {
 var gross = evt.timeStamp - stamp
 var wpm = Math.round(6000/gross)
 document.getElementById("wpm").firstChild.nodeValue = wpm + " wpm."
 }
 stamp = evt.timeStamp
}
</SCRIPT>
</HEAD>
<BODY>

## Chapter 30 Examples

The following sections contain examples from Chapter 30, “Style sheet and Style Objects.”

### styleSheet Object

#### Properties

##### cssRules

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓				(✓)	(✓)

#### Example

Use The Evaluator (Chapter 13) to look at the `cssRules` property in NN6+ or IE5+/Mac. First, view how many rules are in the first `styleSheet` object of the page by entering the following statement into the top text box:

```
document.styleSheets[0].cssRules.length
```

Now use the array with an index value to access one of the rule objects to view the rule object’s properties list. Enter the following statement into the bottom text box:

```
document.styleSheets[0].cssRules[1]
```

You use this syntax to modify the style details of an individual rule belonging to the `styleSheet` object.

##### cssText

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility								✓	✓

### Example

Use The Evaluator (Chapter 13) to replace the style rules in one blast via the `cssText` property. Begin by examining the value returned from the property for the initially disabled style sheet by entering the following statement into the top text box:

```
document.styleSheets[0].cssText
```

Next, enable the style sheet so that its rules are applied to the document:

```
document.styleSheets[0].disabled = false
```

Finally, enter the following statement into the top text box to overwrite the style sheet with entirely new rules.

```
document.styleSheets[0].cssText = "P {color:red}"
```

Reload the page after you are finished to restore the original state.

## disabled

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to toggle between the enabled and disabled state of the first `styleSheet` object on the page. Enter the following statement into the top text box:

```
document.styleSheets[0].disabled = (!document.styleSheets[0].disabled)
```

The inclusion of the NOT operator (!) forces the state to change from `true` to `false` or `false` to `true` with each click of the Evaluate button.

## ownerNode

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) with NN6 to inspect the `ownerNode` of the first `styleSheet` object in the document. Enter the following statement into the top text box:

```
document.styleSheets[0].ownerNode.tagName
```

The returned value is the STYLE element tag name.

## owningElement

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) with IE4+ to inspect the `owningElement` of the first `styleSheet` object in the document. Enter the following statement into the top text box:

```
document.styleSheets[0].owningElement.tagName
```

The returned value is the STYLE element tag name.

## rules

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>							✓	✓	✓

### Example

Use The Evaluator (Chapter 13) with IE4+ to examine the `rules` property of the first `styleSheet` object in the page. First, find out how many rules are in the first `styleSheet` object by entering the following statement into the top text box:

```
document.styleSheets[0].rules.length
```

Next, examine the properties of one of the rules by entering the following statement into the bottom text box:

```
document.styleSheets[0].rules[1]
```

You now see the all the properties that IE4+ exposes for a rule object.

## Methods

```
addRule("selector", "styleSpec"[, index])
removeRule(index)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility							✓	✓	✓

## Example

Use The Evaluator (Chapter 13) with IE4+ to add a style sheet rule to the first `styleSheet` object of the page. First, make sure the style sheet is enabled by entering the following statement into the top text box:

```
document.styleSheets[0].disabled = false
```

Next, append a style that sets the color of the `TEXTAREA` element:

```
document.styleSheets[0].addRule("TEXTAREA", "color:red")
```

Enter any valid object (such as `document.body`) into the bottom text box to see how the style has been applied to the `TEXTAREA` element on the page.

Now remove the style, using the index of the last item of the `rules` collection as the index:

```
document.styleSheets[0].removeRule(document.styleSheets[0].rules.length - 1)
```

The text in the `TEXTAREA` returns to its default color.

```
deleteRule(index)
insertRule("rule", index)
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓					

### Example

Use The Evaluator (Chapter 13) with NN6+ to add a style sheet rule to the first `styleSheet` object of the page. First, make sure the style sheet is enabled by entering the following statement into the top text box:

```
document.styleSheets[0].disabled = false
```

Next, append a style that sets the color of the `TEXTAREA` element:

```
document.styleSheets[0].insertRule("TEXTAREA {color:red}",
document.styleSheets[0].cssRules.length)
```

Enter any valid object (such as `document.body`) into the bottom text box to see how the style has been applied to the `TEXTAREA` element on the page.

Now remove the style, using the index of the last item of the rules collection as the index:

```
document.styleSheets[0].deleteRule(document.styleSheets[0].cssRules.length - 1)
```

The first release of NN6 processes most, but not all, of the internal actions in response to the `deleteRule()` method. The method returns no value, so the Results box after evaluating the `deleteRule()` example statement correctly reports `undefined`. At the same time, the method has genuinely removed the rule from the `styleSheet` object (as proven by inspecting the `length` property of the `document.styleSheets[0].cssRules` array). But the browser does not refresh the page display to reflect the removal of the rule.

# cssRule and rule Objects

## Properties

### selectorText

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to examine the `selectorText` property of rules in the first `styleSheet` object of the page. Enter each of the following statements in the top text box:

```
document.styleSheets[0].rules[0].selectorText
document.styleSheets[0].rules[1].selectorText
```

Compare these values against the source code view for the `STYLE` element in the page.

### style

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>				✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to modify a `style` property of one of the `styleSheet` rules in the page. The syntax shown here is for IE4+, but you can substitute the `cssRules` reference for the `rules` collection reference in NN6 (and IE5/Mac) if you like.

Begin by reloading the page and making sure the style sheet is enabled. Enter the following statement into the top text box:

```
document.styleSheets[0].disabled = false
```

The first rule is for the `myP` element on the page. Change the rule's font-size style:

```
document.styleSheets[0].rules[0].style.fontSize = "20pt"
```

Look over the `style` object properties in the discussion of the `style` object later in this chapter and have fun experimenting with different style properties. After you are finished, reload the page to restore the styles to their default states.

## Chapter 31 Examples

The following sections contain examples from Chapter 31, "Positioned Objects."

### NN4 Layer Object

#### Properties

above  
below  
siblingAbove  
siblingBelow

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility			✓						

#### Example

Listing 31-1 enables you to experiment with just one set of these properties: `layerObject.above` and `layerObject.below`. The page is almost in the form of a laboratory/quiz that enables you to query yourself about the values of these properties for two swappable layers.

**Listing 31-1: A Layer Quiz**

```

<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function checkAbove(oneLayer) {
 document.forms[0].errors.value = ""
 document.forms[0].output.value = oneLayer.above.name
}
function checkBelow(oneLayer) {
 document.forms[0].errors.value = ""
 document.forms[0].output.value = oneLayer.below.name
}
function swapLayers() {
 if (document.yeller.above) {
 document.yeller.moveAbove(document.greeny)
 } else {
 document.greeny.moveAbove(document.yeller)
 }
}
function onerror(msg) {
 document.forms[0].output.value = ""
 document.forms[0].errors.value = msg
 return true
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Layer Ordering</H1>
<HR>
<FORM>
Results:<INPUT TYPE="text" NAME="output"><P>
<INPUT TYPE="button" VALUE="Who's ABOVE the Yellow layer?"
onClick="checkAbove(document.yeller)">

<INPUT TYPE="button" VALUE="Who's BELOW the Yellow layer?"
onClick="checkBelow(document.yeller)"><P>
<INPUT TYPE="button" VALUE="Who's ABOVE the Green layer?"
onClick="checkAbove(document.greeny)">

<INPUT TYPE="button" VALUE="Who's BELOW the Green layer?"
onClick="checkBelow(document.greeny)"><P>
<INPUT TYPE="button" VALUE="Swap Layers" onClick="swapLayers()"><P>
If there are any errors caused by missing

properties, they will appear below:

<TEXTAREA NAME="errors" COLS=30 ROWS=3 WRAP="virtual"></TEXTAREA>
</FORM>
<LAYER NAME="yeller" BGCOLOR="yellow" TOP=110 LEFT=300 WIDTH=200 HEIGHT=200>
This is just a yellow layer.
</LAYER>

```

*Continued*

**Listing 31-1 (continued)**

```
<LAYER NAME="greeny" BGCOLOR="lightgreen" TOP=150 LEFT=340 WIDTH=200 HEIGHT=200>
This is just a green layer.
</LAYER>
</BODY>
</HTML>
```

The page contains two layers: one colored yellow and the other light green. Legends on four buttons ask you to guess whether one layer is above or below the other. For example, if you click the button labeled “Who’s ABOVE the Yellow layer?” and the green layer is above it, the name of that green layer appears in the Results field. But if layers are oriented such that the returned value is `null`, the error message (indicating that the nonexistent object doesn’t have a `name` property) appears in the error field at the bottom. Another button enables you to swap the order of the layers so you can try your hand at predicting the results based on your knowledge of layers and the `above` and `below` properties.

Positioned objects in IE4+ and NN6 have no comparable properties to the four described in this section.

## background

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

A simple example (Listing 31-2) defines one layer that features five buttons to change the background image of a second layer. I put the buttons in a layer because I want to make sure the buttons and background layer rectangles align themselves along their top edges on all platforms.

As the second layer loads, I merely assign a gray background color to it and write some reverse (white) text. Most of the images are of the small variety that repeat in the layer. One is a large photograph to demonstrate how images are clipped to the layer’s rectangle. Along the way, I hope you also heed the lesson of readability demonstrated by the difficulty of reading text on a wild-looking background. For an example compatible with IE5+ and NN6+, see Listing 31-13.

**Listing 31-2: Setting Layer Backgrounds**

```

<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
function setBg(URL) {
 document.bgExpo.background.src = URL
}
</SCRIPT>
</HEAD>
<BODY>
<H1>Layer Backgrounds</H1>
<HR>
<LAYER NAME="buttons" TOP=100>
 <FORM>
 <INPUT TYPE="button" VALUE="The Usual"
onClick="setBg('cr_kraft.gif')">

 <INPUT TYPE="button" VALUE="A Big One" onClick="setBg('arch.gif')">

 <INPUT TYPE="button" VALUE="Not So Usual"
onClick="setBg('wh86.gif')">

 <INPUT TYPE="button" VALUE="Decidedly Unusual"
onClick="setBg('sb23.gif')">

 <INPUT TYPE="button" VALUE="Quick as..."
onClick="setBg('lightnin.gif')">

 </FORM>
</LAYER>
<LAYER NAME="bgExpo" BGCOLOR="gray" TOP=100 LEFT=250 WIDTH=300 HEIGHT=260>
Some text, which may or may not read well with the
various backgrounds.
</LAYER>
</BODY>
</HTML>

```

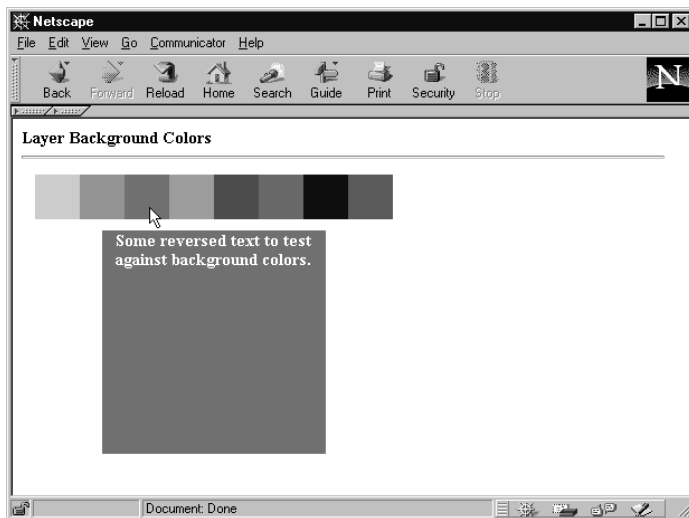

**bgColor**

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

**Example**

You can have some fun with Listing 31-3, which uses a number of layer scripting techniques. The page presents a kind of palette of eight colors, each one created as

a small layer (see Figure 31-1). Another, larger layer's `bgColor` property changes as you roll the mouse over any color in the palette.

**Figure 31-1:** Drag the mouse across the palette to change the layer's background color.

To save HTML lines to create those eight color palette layers, I use a script to establish an array of colors and then `document.write()` the `<LAYER>` tags with appropriate attribute settings so the layers all line up in a contiguous row. By predefining a number of variable values for the size of the color layers, I can make all of them larger or smaller with the change of only a few script characters.

The document object handles the job of capturing the `mouseover` events. I turn on the document's `captureEvents()` method such that it traps all `mouseover` events and hands them to the `setColor()` function. The `setColor()` function reads the target object's `bgColor` and sets the larger layer's `bgColor` property to the same. If this page had other objects that could receive `mouseover` events for other purposes, I would use `routeEvents()` to let those events pass on to their intended targets. For the purposes of this example, however, the events need to go no further. Listing 31-14 shows the same functionality working in IE5+ and NN6+.

### Listing 31-3: Layer Background Colors

```
<HTML>
<HEAD>
<SCRIPT LANGUAGE="JavaScript">
```

```

function setColor(e) {
 document.display.bgColor = e.target.bgColor
}
document.captureEvents(Event.MOUSEOVER)
document.onmouseover = setColor
</SCRIPT>
</HEAD>
<BODY>
<H1>Layer Background Colors</H1>
<HR>
<SCRIPT LANGUAGE="JavaScript">
var oneLayer
var colorTop = 100
var colorLeft = 20
var colorWidth = 40
var colorHeight = 40
var colorPalette = new
Array("aquamarine","coral","forestgreen","goldenrod","red",
 "magenta","navy","teal")
for (var i = 0; i < colorPalette.length; i++) {
 oneLayer = "<LAYER NAME=swatch" + i + " TOP=" + colorTop
oneLayer += " LEFT=" + ((colorWidth * i) + colorLeft)
oneLayer += " WIDTH=" + colorWidth + " HEIGHT=" + colorHeight
oneLayer += " BGCOLOR=" + colorPalette[i] + "></LAYER>\n"
 document.write(oneLayer)
}
</SCRIPT>
<LAYER NAME="display" BGCOLOR="gray" TOP=150 LEFT=80 WIDTH=200 HEIGHT=200>
<CENTER>Some reversed text to test against background
colors.</CENTER>
</LAYER>
</BODY>
</HTML>

```

## clip

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

Because of the edge movement behavior of adjustments to `layerObject.clip` properties, Listing 31-4 enables you to experiment with adjustments to each of the

six properties. The document loads one layer that you can adjust by entering alternative values into six text fields — one per property. Figure 31-2 shows the page.

**Figure 31-2:** Experiment with `layer.clip` properties.

As you enter values, all properties are updated to show their current values (via the `showValues()` function). Pay particular attention to the apparent motion of the edge and the effect the change has on at least one other property. For example, a change to the `layerObject.clip.left` value also affects the `layerObject.clip.width` property value.

### Listing 31-4: Adjusting `layer.clip` Properties

```
<HTML>
<HEAD>
<TITLE>Layer Clip</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var origLayerWidth = 0
var origLayerHeight = 0
function initializeXY() {
 origLayerWidth = document.display.clip.width
 origLayerHeight = document.display.clip.height
 showValues()
}
}
```

```

function setClip(field) {
 var clipVal = parseInt(field.value)
 document.display.clip[field.name] = clipVal
 showValues()
}
function showValues() {
 var form = document.layers[0].document.forms[0]
 var propName
 for (var i = 0; i < form.elements.length; i++) {
 propName = form.elements[i].name
 if (form.elements[i].type == "text") {
 form.elements[i].value = document.display.clip[propName]
 }
 }
}
var intervalID
function revealClip() {
 var midWidth = Math.round(origLayerWidth / 2)
 var midHeight = Math.round(origLayerHeight / 2)
 document.display.clip.left = midWidth
 document.display.clip.top = midHeight
 document.display.clip.right = midWidth
 document.display.clip.bottom = midHeight
 intervalID = setInterval("stepClip()",1)
}
function stepClip() {
 var widthDone = false
 var heightDone = false
 if (document.display.clip.left > 0) {
 document.display.clip.left += -2
 document.display.clip.right += 2
 } else {
 widthDone = true
 }
 if (document.display.clip.top > 0) {
 document.display.clip.top += -1
 document.display.clip.bottom += 1
 } else {
 heightDone = true
 }
 showValues()
 if (widthDone && heightDone) {
 clearInterval(intervalID)
 }
}
</SCRIPT>
</HEAD>
<BODY onLoad="initializeXY()">

</P>
</LAYER>
</BODY>
</HTML>

```

Listing 31-4 has a lot of other scripting in it to demonstrate a couple of other clip area techniques. After the document loads, the `onLoad` event handler initializes two global variables that represent the starting height and width of the layer as determined by the `clip.height` and `clip.width` properties. Because the `<LAYER>` tag does not specify any CLIP attributes, the `layerObject.clip` region is ensured of being the same as the layer's dimensions at load time.

I preserve the initial values for a somewhat advanced set of functions that act in response to the Reveal Original Layer button. The goal of this button is to temporarily shrink the clipping area to nothing and then expand the clip rectangle gradually from the very center of the layer. The effect is analogous to a zoom-out visual effect.

The clip region shrinks to practically nothing by setting all four edges to the same point midway along the height and width of the layer. The script then uses `setInterval()` to control the animation in `setClip()`. To make the zoom even on both axes, I first make sure that the initial size of the layer is an even ratio: twice as wide as it is tall. Each time through the `setClip()` function, the `clip.left` and `clip.right` values are adjusted in their respective directions by two pixels and `clip.top` and `clip.bottom` are adjusted by one pixel.

To make sure the animation stops when the layer is at its original size, I check whether the `clip.top` and `clip.left` values are their original zero values. If they are, I set a Boolean variable for each side. When both variables indicate that the clip rectangle is its original size, the script cancels the `setInterval()` action.

Listing 31-15 demonstrates how to adjust clipping in IE5+ and NN6+ syntax.

left  
top

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

To enable you to experiment with manually setting `layerObject.top` and `layerObject.left` properties, Listing 31-5 is a modified version of the `layer.clip` example (Listing 31-4). The current example again has the one modifiable layer, but it has only four text fields in which you can enter values. Two fields are for the `layerObject.left` and `layerObject.top` properties; the other two are for the `layerObject.clip.left` and `layerObject.clip.top` properties. I present both sets of values here to help reinforce the lack of connection between layer and clip location properties in the same layer object.

You can find the corresponding syntax for IE5+ and NN6+ in Listing 31-16.

### Listing 31-5 Comparison of Layer and Clip Location Properties

## Example

Listing 31-6 defines one outer layer and one nested inner layer of different colors (see Figure 31-3). The inner layer contains some text content; the outer layer is sized initially to present a colorful border by being below the inner layer and 10 pixels wider and taller.

Two sets of fields display (and enable you to change) the `layerObject.pageX`, `layerObject.pageY`, `layerObject.left`, and `layerObject.top` properties for each of the nested layers. Each set of fields is color-coded to its corresponding layer.

When you change any value, all values are recalculated and displayed in the other fields. For example, the initial `pageX` position for the outer layer is 200 pixels; for the inner layer, the `pageX` value is 205 pixels (accounting for the 5-pixel “border” around the inner layer). If you change the outer layer’s `pageX` value to 220, the outer layer moves to the right by 20 pixels, taking the inner layer along for the ride. The `layer.pageX` value for the inner layer after the move is 225 pixels.

**Figure 31-3:** Testing the position properties of nested layers

The outer layer values for the pairs of values are always the same no matter what. But for the inner layer, the page values are significantly different from the `layer.left` and `layer.top` values because these latter values are measured relative to their containing layer—the outer layer. If you move the outer layer, the inner layer values for `layerObject.left` and `layerObject.top` don't change one iota. Listing 31-17 shows the comparable syntax for IE5+ and NN6+.

### Listing 31-6: Testing Nested Layer Coordinate Systems

```
<HTML>
<HEAD>
<TITLE>Nested Layer PageX/PageY</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function setOuterPage(field) {
 var layerVal = parseInt(field.value)
 document.outerDisplay[field.name] = layerVal
 showValues()
}
function setOuterLayer(field) {
 var layerVal = parseInt(field.value)
 document.outerDisplay[field.name] = layerVal
 showValues()
}
function setInnerPage(field) {
 var layerVal = parseInt(field.value)
```

```

 document.outerDisplay.document.innerDisplay[field.name] = layerVal
 showValues()
 }
 function setInnerLayer(field) {
 var layerVal = parseInt(field.value)
 document.outerDisplay.document.innerDisplay[field.name] = layerVal
 showValues()
 }
 function showValues() {
 var form = document.layers[0].document.forms[0]
 form.elements[0].value = document.outerDisplay.pageX
 form.elements[1].value = document.outerDisplay.pageY
 form.elements[2].value = document.outerDisplay.left
 form.elements[3].value = document.outerDisplay.top
 form.elements[4].value = document.outerDisplay.document.innerDisplay.pageX
 form.elements[5].value = document.outerDisplay.document.innerDisplay.pageY
 form.elements[6].value = document.outerDisplay.document.innerDisplay.left

<b>Compatibility</b>			✓						

## Example

Setting the `layerObject.src` property of a layer that is a member of a layer family (that is, a family with at least one parent and one child) can be tricky business if you're not careful. Listing 31-7 presents a workspace for you to see how changing the `src` property of outer and inner layers affects the scenery.

When you first load the document, one outer layer contains one inner layer (each with a different background color). Control buttons on the page enable you to set the `layerObject.src` property of each layer independently. Changes to the inner layer content affect only that layer. Long content forces the inner layer to expand its depth, but the inner layer's view is automatically clipped by its parent layer.

Changing the outer layer content, however, removes the inner layer completely. Code in the following listing shows one way to examine for the presence of a particular layer before attempting to load new content in it. If the inner layer doesn't exist, the script creates a new layer on the fly to replace the original inner layer.

### Listing 31-7: Setting Nested Layer Source Content

```
<HTML>
<HEAD>
<TITLE>Layer Source</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function loadOuter(doc) {
 document.outerDisplay.src = doc
}
function loadInner(doc) {
 var nested = document.outerDisplay.document.layers
 if (nested.length > 0) {
 // inner layer exists, so load content or restore
 if (doc) {
 nested[0].src = doc
 } else {
 restoreInner(nested[0])
 }
 } else {
 // prompt user about restoring inner layer
 if (confirm("The inner layer has been removed by loading an outer
document. " + "Restore the original layers?")) {
 restoreLayers(doc)
 }
 }
}
function restoreLayers(doc) {
 // reset appearance of outer layer
 document.outerDisplay.bgColor = "coral"
```

*Continued*

## Listing 31-7 (continued)

```

document.outerDisplay.resizeTo(370,190) // sets clip
document.outerDisplay.document.write("")
document.outerDisplay.document.close()
// generate new inner layer
var newInner = new Layer(360, document.layers["outerDisplay"])
newInner.bgColor = "aquamarine"
newInner.moveTo(5,5)
if (doc) {
 // user clicked an inner content button
 newInner.src = doc
} else {
 // return to pristine look
 restoreInner(newInner)
}
newInner.visibility = "show"
}
function restoreInner(inner) {
 inner.document.write("<HTML><BODY><P>Placeholder text for raw inner
layer.</P>" + 0"</BODY></HTML>")
 inner.document.close()
 inner.resizeTo(360,180) // sets clip
}
</SCRIPT>
</HEAD>
<BODY>
Setting the <TT>layer.src</TT> Property of Nested Layers
<HR>
Click the buttons to see what happens when you load new source documents into
the outer layer and inner
layer objects.<P>
<LAYER TOP=100 BGCOLOR="coral">
<FORM>
Load into outer layer:

<INPUT TYPE="button" VALUE="Article I" onClick="loadOuter('article1.htm')">

<INPUT TYPE="button" VALUE="Entire Bill of Rights"
onClick="loadOuter('bofright.htm')">

</FORM>
</LAYER>
<LAYER TOP=220 BGCOLOR="aquamarine">
<FORM>
Load into inner layer:

<INPUT TYPE="button" VALUE="Article I" onClick="loadInner('article1.htm')">

<INPUT TYPE="button" VALUE="Entire Bill of Rights"
onClick="loadInner('bofright.htm')">

<INPUT TYPE="button" VALUE="Restore Original" onClick="loadInner()">

</FORM>
</LAYER>
<LAYER NAME="outerDisplay" BGCOLOR="coral" TOP=100 LEFT=200 WIDTH=370

```

<LAYER NAME="innerDisplay" BGCOLOR="aquamarine" TOP=5 LEFT=5 WIDTH=360
HEIGHT=180>
 <P>Placeholder text for raw inner layer.</P>
</LAYER>
</LAYER>
</BODY>
</HTML>

```

Restoring the original layers via script (as opposed to reloading the document) does not perform a perfect restoration. The key difference is that the scripts use the `layerObject.resizeTo()` method to set the layers to the height and width established by the `<LAYER>` tags that create the layers in the first place. This method, however, sets the clipping rectangle of the layer — not the layer's size. Therefore, if you use the script to restore the layers, loading the longer text file into either layer does not force the layer to expand to display all the content; the clipping region governs the view.

## visibility

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

Use the page in Listing 31-8 to see how the `layerObject.visibility` property settings affect a pair of nested layers. When the page first loads, the default `inherit` setting is in effect. Changes you make to the outer layer by clicking the outer layer buttons affect the inner layer, but setting the inner layer's properties to `hide` or `show` severs the visibility relationship between parent and child. Listing 31-19 shows this example with IE5+ and NN6+ syntax.

### Listing 31-8: Nested Layer Visibility Relationships

```

## zIndex

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

## Example

The relationships among the three stacking property values can be difficult to visualize. Listing 31-9 offers a way to see the results of changing the `layerObject.zIndex` properties of three overlapping sibling layers. Figure 31-4 shows the beginning organization of layers after the page loads.

**Figure 31-4:** A place to play with `zIndex` property settings

The sequence of the `<LAYER>` tags in the document governs the original stacking order. Because the attribute is not set in the HTML, the initial values appear as zero for all three layers. But, as the page reveals, the `layerObject.above` and `layerObject.below` properties are automatically established. When a layer has no other layer object above it, the page shows `(none)`. Also, if the layer below the bottom of the stack is the main window, a strange inner layer name is assigned (something like `_js_layer_21`).

To experiment with this page, first make sure you understand the `layerObject.above` and `layerObject.below` readings for the default order of the layers. Then, assign different orders to the layers with value sequences such as 3-2-1, 1-3-2, 2-2-2, and so on. Each time you enter one new value, check the actual layers to see if their stacking order changed and how that affected the other properties of all layers.

Listing 31-20 shows how to achieve the same action with IE5+ and NN6+ syntax.

### Listing 31-9: Relationships Among zIndex, above, and below

```

<HTML>
<HEAD>
<TITLE>Layer zIndex</TITLE>

## Methods

`load("URL", newLayerWidth)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

Buttons in Listing 31-10 enable you to load short and long documents into a layer. The first two buttons don't change the width (in fact, the second parameter to `layerObject.load()` is the `layerObject.clip.left` value). For the second two buttons, a narrower width than the original is specified. Click the Restore button frequently to return to a known state.

#### Listing 31-10: Loading Documents into Layers

```
<HTML>
<HEAD>
<TITLE>Layer Loading</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function loadDoc(URL,width) {
 if (!width) {
 width = document.myLayer.clip.width
 }
 document.myLayer.load(URL, width)
}
</SCRIPT>
</HEAD>
<BODY>
Loading New Documents
<HR>

```

`moveAbove(layerObject)`  
`moveBelow(layerObject)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

You can see the `layerObject.moveAbove()` method at work in Listing 31-1.

`moveBy(deltaX,deltaY)`  
`moveTo(x,y)`  
`moveToAbsolute(x,y)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

Listing 31-11 shows a demonstration of the `layerObject.moveTo()` method. It is a simple script that enables you to click and drag a layer around the screen. The script employs the coordinate values of the `mousemove` event; after compensating for the offset within the layer at which the click occurs, the script moves the layer to track the mouse action.

I want to present this example for an additional reason: to explain an important user interface difference between Windows and Macintosh versions of NN4. In Windows versions, you can click and hold the mouse button down on an object and let the object receive all the `mousemove` events as you drag the cursor around the screen. On the Macintosh, however, NN4 tries to compensate for the lack of a second mouse

button by popping up a context-sensitive menu at the cursor position when the user holds the mouse button down for more than just a click. To prevent the pop-up menu from appearing, the `engage()` method invoked by the `onMouseDown` event handler ends with `return false`.

Notice in the following listing how the layer captures a number of mouse events. Each one plays an important role in creating a mode that is essentially like a `mouseStillDown` event (which doesn't exist in NN4's event model). The `mousedown` event sets a Boolean flag (`engaged`) indicating that the user clicked down in the layer. At the same time, the script records how far away from the layer's top-left corner the `mousedown` event occurred. This offset information is needed so that any setting of the layer's location takes this offset into account (otherwise, the top-left corner of the layer would jump to the cursor position and be dragged from there).

During the drag (`mousedown` events firing with each mouse movement), the `dragIt()` function checks whether the drag mode is engaged. If so, the layer is moved to the page location calculated by subtracting the original downstroke offset from the `mousemove` event location on the page. When the user releases the mouse button, the `mouseup` event turns off the drag mode Boolean value.

Listing 31-21 shows a version of this example for IE5+ and NN6.

### Listing 31-11: Dragging a Layer

```
<HTML>
<HEAD>
<TITLE>Layer Dragging</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var engaged = false
var offsetX = 0
var offsetY = 0
function dragIt(e) {
 if (engaged) {
 document.myLayer.moveTo(e.pageX - offsetX, e.pageY - offsetY)
 }
}
function engage(e) {
 engaged = true
 offsetX = e.pageX - document.myLayer.left
 offsetY = e.pageY - document.myLayer.top
 return false
}
function release() {
 engaged = false
}
</SCRIPT>
</HEAD>
<BODY>
```

document.myLayer.onMouseDown = engage
document.myLayer.onMouseUp = release
document.myLayer.onMouseMove = dragIt
</SCRIPT>
</BODY>
</HTML>

```

`resizeBy(deltaX,deltaY)`  
`resizeTo(width,height)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓						

### Example

It is important to understand the ramifications of content flow when these two methods resize a layer. Listing 31-12a (and the companion document Listing 31-12b) shows you how to set the lower-right corner of a layer to be dragged by a user for resizing the layer (much like grabbing the resize corner of a document window). Three radio buttons enable you to choose whether and when the content should be redrawn to the layer — never, after resizing, or during resizing.

Event capture is very much like that in Listing 31-11 for layer dragging. The primary difference is that drag mode is engaged only when the mouse event takes place in the region of the lower-right corner. A different kind of offset value is saved here because, for resizing, the script needs to know the mouse event offset from the right and bottom edges of the layer.

Condition statements in the `resizeIt()` and `release()` functions verify whether a specific radio button is checked to determine when (or if) the content should be redrawn. I designed this page with the knowledge that its content might be redrawn. Therefore, I built the content of the layer as a separate HTML document that loads in the `<LAYER>` tag.

Redrawing the content requires reloading the document into the layer. I use the `layerObject.load()` method because I want to send the current `layerObject.clip.width` as a parameter for the width of the clip region to accommodate the content as it loads.

An important point to know about reloading content into a layer is that all property settings for the layer's event capture are erased when the document loads. Overcoming this behavior requires setting the layer's `onLoad` event handler to set the layer's event capture mechanism. If the layer event capturing is specified as part of the statements at the end of the document, the layer ignores some important events needed for the dynamic resizing after the document reloads the first time.

As you experiment with the different ways to resize and redraw, you see that redrawing during resizing is a slow process because of the repetitive loading (from cache) needed each time. On slower client machines, it is easy for the cursor to outrun the layer region, causing the layer to not get `mouseover` events at all. It may not be the best-looking solution, but I prefer to redraw after resizing the layer.

Listing 31-22 shows a version designed for the IE5+ and NN6 object models. Because content automatically reflows in those browsers, you do not have to load the content of the positioned element from an external document.

### Listing 31-12a: Resizing a Layer

```
<HTML>
<HEAD>
<TITLE>Layer Resizing</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var engaged = false
var offsetX = 0
var offsetY = 0
function resizeIt(e) {
 if (engaged) {
 document.myLayer.resizeTo(e.pageX + offsetX, e.pageY + offsetY)
 if (document.forms[0].redraw[2].checked) {
 document.myLayer.load("lst31-12b.htm", document.myLayer.clip.width)
 }
 }
}
function engage(e) {
 if (e.pageX > (document.myLayer.clip.right - 10) &&
 e.pageY > (document.myLayer.clip.bottom - 10)) {
 engaged = true
 offsetX = document.myLayer.clip.right - e.pageX
 offsetY = document.myLayer.clip.bottom - e.pageY
 }
}
}
```

```

function release() {
 if (engaged && document.forms[0].redraw[1].checked) {
 document.myLayer.load("1st31-12b.htm", document.myLayer.clip.width)
 }
 engaged = false
}

```

## Chapter 34 Examples

The following section contains examples from Chapter 34, “The String Object.”

### String Object

#### Properties

##### constructor

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

#### Example

Use The Evaluator (Chapter 13) to test the value of the `constructor` property. Enter the following statements into the top text box:

```
a = new String("abcd")
a.constructor == String
a.constructor == Number
```

#### Parsing methods

##### *string.charAt(index)*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

#### Example

Enter each of the following statements into the top text box of The Evaluator:

```
a = "banana daiquiri"
a.charAt(0)
```

```
a.charAt(5)
a.charAt(6)
a.charAt(20)
```

Results from each of the `charAt()` methods should be b, a (the third “a” in “banana”), a space character, and an empty string, respectively.

```
string.charCodeAt([index])
String.fromCharCode(num1 [, num2 [, ...
numn]])
```

**Returns:** Integer code number for a character; concatenated string value of code numbers supplied as parameters.

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

## Example

Listing 34-2 provides examples of both methods on one page. Moreover, because one of the demonstrations relies on the automatic capture of selected text on the page, the scripts include code to accommodate the different handling of selection events and capture of the selected text in Navigator and Internet Explorer 4.

After you load the page, select part of the body text anywhere on the page. If you start the selection with the lowercase letter “a,” the character code displays as 97. If you select no text, the result is NaN.

Try entering numeric values in the three fields at the bottom of the page. Values below 32 are ASCII control characters that most fonts represent as hollow squares. But try all other values to see what you get. Notice that the script passes all three values as a group to the `String.fromCharCode()` method, and the result is a combined string.

**Listing 34-2: Character Conversions**

```

<HTML>
<HEAD>

*string.indexOf(searchString [, startIndex])*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Enter each of the following statements (up to, but not including the “//” comment symbols) into the top text box of The Evaluator (you can simply replace the parameters of the `indexOf()` method for each statement after the first one). Compare your results with the results shown below.

```
a = "bananas"
a.indexOf("b") // result = 0 (index of first letter is zero)
a.indexOf("a") // result = 1
a.indexOf("a",1) // result = 1 (start from second letter)
a.indexOf("a",2) // result = 3 (start from third letter)
a.indexOf("a",4) // result = 5 (start from fifth letter)
a.indexOf("nan") // result = 2
a.indexOf("nas") // result = 4
a.indexOf("s") // result = 6
a.indexOf("z") // result = -1 (no "z" in string)
```

*string.lastIndexOf(searchString[, startIndex])*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Enter each of the following statements (up to, but not including the “//” comment symbols) into the top text box of The Evaluator (you can simply replace the parameters of the `lastIndexOf()` method for each statement after the first one). Compare your results with the results shown below.

```
a = "bananas"
a.lastIndexOf("b") // result = 0 (index of first letter is zero)
a.lastIndexOf("a") // result = 5
a.lastIndexOf("a",1) // result = 1 (from second letter toward the front)
```

```

a.lastIndexOf("a",2) // result = 1 (start from third letter working to front)
a.lastIndexOf("a",4) // result = 3 (start from fifth letter)
a.lastIndexOf("nan") // result = 2 [except for -1 Nav 2.0 bug]
a.lastIndexOf("nas") // result = 4
a.lastIndexOf("s") // result = 6
a.lastIndexOf("z") // result = -1 (no "z" in string)

```

## *string.match(regExpression)*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

To help you understand the `string.match()` method, Listing 34-3 provides a workshop area for experimentation. Two fields occur for data entry: the first is for the long string to be examined by the method; the second is for a regular expression. Some default values are provided in case you're not yet familiar with the syntax of regular expressions (see Chapter 38). A check box lets you specify whether the search through the string for matches should be case-sensitive. After you click the "Execute match()" button, the script creates a regular expression object out of your input, performs the `string.match()` method on the big string, and reports two kinds of results to the page. The primary result is a string version of the array returned by the method; the other is a count of items returned.

### Listing 34-3: Regular Expression Match Workshop

```

<HTML>
<HEAD>
<TITLE>Regular Expression Match</TITLE>
<SCRIPT LANGUAGE="JavaScript">
function doMatch(form) {
 var str = form.entry.value
 var delim = (form.caseSens.checked) ? "/"g" : "/"gi"
 var regexp = eval("/" + form.regexp.value + delim)
 var resultArray = str.match(regexp)
 if (resultArray) {
 form.result.value = resultArray.toString()
 form.count.value = resultArray.length
 } else {
 form.result.value = "<no matches>"
 form.count.value = ""
 }
}

```

```

</SCRIPT>
</HEAD>
<BODY>
String Match with Regular Expressions
<HR>
<FORM>
Enter a main string:<INPUT TYPE="text" NAME="entry" SIZE=60
 VALUE="Many a maN and womAN have meant to visit GerMAny.">

Enter a regular expression to match:<INPUT TYPE="text" NAME="regexp" SIZE=25
 VALUE="\wa\w">
<INPUT TYPE="checkbox" NAME="caseSens">Case-sensitive<P>
<INPUT TYPE="button" VALUE="Execute match()" onClick="doMatch(this.form)">
<INPUT TYPE="reset"><P>
Result:<INPUT TYPE="text" NAME="result" SIZE=40>

Count:<INPUT TYPE="text" NAME="count" SIZE=3>

</FORM>
</BODY>
</HTML>

```

The default value for the main string has unusual capitalization intentionally. The capitalization lets you see more clearly where some of the matches come from. For example, the default regular expression looks for any three-character string that has the letter “a” in the middle. Six string segments match that expression. With the help of capitalization, you can see where each of the four strings containing “man” are extracted from the main string. The following table lists some other regular expressions to try with the default main string.

<b>RegExp</b>	<b>Description</b>
man	Both case-sensitive and not
man\b	Where “man” is at the end of a word
\bman	Where “man” is at the start of a word
me*an	Where zero or more “e” letters occur between “m” and “a”
.a.	Where “a” is surrounded by any one character (including space)
\sa\s	Where “a” is surrounded by a space on both sides
z	Where a “z” occurs (none in the default string)

In the scripts for Listing 34-3, if the `string.match()` method returns `null`, you are informed politely, and the count field is emptied.

*string.replace(regExpression, replaceString)*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

**Example**

The page in Listing 34-4 lets you practice with the `string.replace()` and `string.search()` methods and regular expressions in a friendly environment. The source text is a five-line excerpt from *Hamlet*. You can enter the regular expression to search for, and the replacement text as well. Note that the script completes the job of creating the regular expression object, so that you can focus on the other special characters used to define the matching string. All replacement activities act globally, because the `g` parameter is automatically appended to any expression you enter.

Default values in the fields replace the contraction ‘tis with “it is” after you click the “Execute replace()” button. Notice that the backslash character in front of the apostrophe of ‘tis (in the string assembled in `mainString`) makes the apostrophe a non-word boundary, and thus allows the `\B't` regular expression to find a match there. As described in the section on the `string.search()` method, the button connected to that method returns the offset character number of the matching string (or `-1` if no match occurs).

You could modify the listing so that it actually replaces text in the HTML paragraph for IE4+ and NN6. The steps include wrapping the paragraph in its own element (for example, a `SPAN`), and invoking the `replace()` method on the `innerHTML` of that element. Assign the results to the `innerHTML` property of that element to complete the job.

**Listing 34-4: Lab for `string.replace()` and `string.search()`**

```
<HTML>
<HEAD>
<TITLE>Regular Expression Replace and Search</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var mainString = "To be, or not to be: that is the question:\n"
mainString += "Whether 'tis nobler in the mind to suffer\n"
mainString += "The slings and arrows of outrageous fortune,\n"
mainString += "Or to take arms against a sea of troubles,\n"
mainString += "And by opposing end them."
```

```

function doReplace(form) {
 var replaceStr = form.replaceEntry.value
 var delim = (form.caseSens.checked) ? "/"g" : "/"gi"
 var regexp = eval("/" + form.regexp.value + delim)
 form.result.value = mainString.replace(regexp, replaceStr)
}
function doSearch(form) {
 var replaceStr = form.replaceEntry.value
 var delim = (form.caseSens.checked) ? "/"g" : "/"gi"
 var regexp = eval("/" + form.regexp.value + delim)
 form.result.value = mainString.search(regexp)
}
</SCRIPT>
</HEAD>

```

## *string.search(regExpression)*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

**Example**

Listing 34-4, for the `string.replace()` method, also provides a laboratory to experiment with the `string.search()` method.

`string.slice(startIndex [, endIndex])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

**Example**

With Listing 34-5, you can try several combinations of parameters with the `string.slice()` method (see Figure 34-1). A base string is provided (along with character measurements). Select from the different choices available for parameters and study the outcome of the slice.

**Listing 34-5: Slicing a String**

```
<HTML>
<HEAD>
<TITLE>String Slicing and Dicing, Part I</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var mainString = "Electroencephalograph"
function showResults() {
 var form = document.forms[0]
 var param1 = parseInt(form.param1.options[form.param1.selectedIndex].value)
 var param2 = parseInt(form.param2.options[form.param2.selectedIndex].value)
 if (!param2) {
 form.result1.value = mainString.slice(param1)
 } else {
 form.result1.value = mainString.slice(param1, param2)
 }
}
</SCRIPT>
</HEAD>
<BODY onLoad="showResults()">

**Figure 34-1:** Lab for exploring the string.slice() method

```
string.split("delimiterCharacter" [,
limitInteger])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓			✓	✓	✓

### Example

Use The Evaluator (Chapter 13) to see how the `string.split()` method works. Begin by assigning a comma-delimited string to a variable:

```
a = "Anderson,Smith,Johnson,Washington"
```

Now split the string at comma positions so that the string pieces become items in an array, saved as `b`:

```
b = a.split(",")
```

To prove that the array contains four items, inspect the array's `length` property:

```
b.length // result: 4
```

```
string.substr(start [, length])
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

Listing 34-6 lets you experiment with a variety of values to see how the `string.substr()` method works.

#### Listing 34-6: Reading a Portion of a String

```
<HTML>
<HEAD>
<TITLE>String Slicing and Dicing, Part II</TITLE>
```

```

<SCRIPT LANGUAGE="JavaScript">
var mainString = "Electroencephalograph"
function showResults() {
 var form = document.forms[0]
 var param1 = parseInt(form.param1.options[form.param1.selectedIndex].value)
 var param2 = parseInt(form.param2.options[form.param2.selectedIndex].value)
 if (!param2) {
 form.result1.value = mainString.substr(param1)
 } else {
 form.result1.value = mainString.substr(param1, param2)
 }
}
</SCRIPT>
</HEAD>
<BODY onLoad="showResults()">

```

`string.substring(indexA, indexB)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

Listing 34-7 lets you experiment with a variety of values to see how the `string.substring()` method works. If you are using Navigator 4, try changing the `LANGUAGE` attribute of the script to `JavaScript1.2` and see the different behavior when you set the parameters to 5 and 3. The parameters switch themselves, essentially letting the second index value become the beginning of the extracted substring.

#### Listing 34-7: Reading a Portion of a String

```
<HTML>
<HEAD>
<TITLE>String Slicing and Dicing, Part III</TITLE>
<SCRIPT LANGUAGE="JavaScript">
var mainString = "Electroencephalograph"
function showResults() {
 var form = document.forms[0]
 var param1 = parseInt(form.param1.options[form.param1.selectedIndex].value)
 var param2 = parseInt(form.param2.options[form.param2.selectedIndex].value)
 if (!param2) {
 form.result1.value = mainString.substring(param1)
 } else {
 form.result1.value = mainString.substring(param1, param2)
 }
}
</SCRIPT>
</HEAD>
<BODY onLoad="showResults()">

</FORM>
</TABLE>
</BODY>
</HTML>

```

*string.toLowerCase()*  
*string.toUpperCase()*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>	✓	✓	✓	✓	✓	✓	✓	✓	✓

### Example

You can use the `toLowerCase()` and `toUpperCase()` methods on literal strings, as follows:

```

var newString = "HTTP://www.Netscape.COM".toLowerCase()
// result = "http://www.netscape.com"

```

The methods are also helpful in comparing strings when case is not important, as follows:

```

if (guess.toUpperCase() == answer.toUpperCase()) {...}
// comparing strings without case sensitivity

```

```
string.toString()
string.valueOf()
```

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Examples

Use The Evaluator to test the `valueOf()` method. Enter the following statements into the top text box and examine the values that appear in the Results field:

```
a = new String("hello")
typeof a
b = a.valueOf()
typeof b
```

Because all other JavaScript core objects also have the `valueOf()` method, you can build generic functions that receive a variety of object types as parameters, and the script can branch its code based on the type of value that is stored in the object.

## Chapter 35 Examples

The following section contains examples from Chapter 35, “The Math, Number, and Boolean Objects.”

# Number Object

## Properties

MAX\_VALUE  
MIN\_VALUE  
NEGATIVE\_INFINITY  
POSITIVE\_INFINITY

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility		✓	✓	✓		✓	✓	✓	✓

## Example

Enter each of the four `Number` object expressions into the top text field of The Evaluator to see how the browser reports each value.

## Methods

`number.toExponential(fractionDigits)`  
`number.toFixed(fractionDigits)`  
`number.toPrecision(precisionDigits)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
Compatibility				✓					✓

## Example

You can use The Evaluator to experiment with all three of these methods with a variety of parameter values. Before invoking any method, be sure to assign a numeric value to one of the built-in global variables in The Evaluator (a through z). None of these methods works with number literals (for example, `123.toExponential(2)` does not work).

`number.toString([radix])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓		✓	✓	✓	✓

### Example

Use The Evaluator to experiment with the `toString()` method. Assign the number 12 to the variable `a` and see how the number is converted to strings in a variety of number bases:

```
a = 12
a.toString() // base 10
a.toString(2)
a.toString(16)
```

## Chapter 37 Examples

The following section contains examples from Chapter 37, “The Array Object.”

## Array Object Methods

`array.concat(array2)`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>			✓	✓			✓	✓	✓

### Example

Listing 37-6 is a bit complex, but it demonstrates both how arrays can be joined with the `array.concat()` method and how values and objects in the source arrays do or do not propagate based on their data type. The page is shown in Figure 37-1.

**Figure 37-1:** Object references remain “alive” in a concatenated array.

After you load the page, you see readouts of three arrays. The first array consists of all string values; the second array has two string values and a reference to a form object on the page (a textbox named “original” in the HTML). In the initialization routine of this page, not only are the two source arrays created, but they are joined with the `array.concat()` method, and the result is shown in the third box. To show the contents of these arrays in columns, I use the `array.join()` method, which brings the elements of an array together as a string delimited in this case by a return character — giving us an instant column of data.

Two series of fields and buttons let you experiment with the way values and object references are linked across concatenated arrays. In the first group, if you enter a new value to be assigned to `arrayThree[0]`, the new value replaces the string value in the combined array. Because regular values do not maintain a link back to the original array, only the entry in the combined array is changed. A call to `showArrays()` proves that only the third array is affected by the change.

More complex is the object relationship for this demonstration. A reference to the first text box of the second grouping has been assigned to the third entry of `arrayTwo`. After concatenation, the same reference is now in the last entry of the combined array. If you enter a new value for a property of the object in the last slot of `arrayThree`, the change goes all the way back to the original object—the first text box in the lower

grouping. Thus, the text of the original field changes in response to the change of `arrayThree[5]`. And because all references to that object yield the same result, the reference in `arrayTwo[2]` points to the same text object, yielding the same new answer. The display of the array contents doesn't change, because both arrays still contain a reference to the same object (and the `VALUE` attribute showing in the `<INPUT>` tag of the column listings refers to the default value of the tag, not to its current algorithmically retrievable value shown in the last two fields of the page).

### Listing 37-6: Array Concatenation

```
<HTML>
<HEAD>
<TITLE>Array Concatenation</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
// global variables
var arrayOne, arrayTwo, arrayThree, textObj
// initialize after load to access text object in form
function initialize() {
 var form = document.forms[0]
 textObj = form.original
 arrayOne = new Array("Jerry", "Elaine","Kramer")
 arrayTwo = new Array("Ross", "Rachel",textObj)
 arrayThree = arrayOne.concat(arrayTwo)
 update1(form)
 update2(form)
 showArrays()
}
// display current values of all three arrays
function showArrays() {
 var form = document.forms[0]
 form.array1.value = arrayOne.join("\n")
 form.array2.value = arrayTwo.join("\n")
 form.array3.value = arrayThree.join("\n")
}
// change the value of first item in Array Three
function update1(form) {
 arrayThree[0] = form.source1.value
 form.result1.value = arrayOne[0]
 form.result2.value = arrayThree[0]
 showArrays()
}
// change value of object property pointed to in Array Three
function update2(form) {
 arrayThree[5].value = form.source2.value
 form.result3.value = arrayTwo[2].value
 form.result4.value = arrayThree[5].value
 showArrays()
}
}
```

```

</SCRIPT>
</HEAD>
<BODY onLoad="initialize()">

<INPUT TYPE="button" VALUE="Reset" onClick="location.reload()">
</FORM>
</BODY>
</HTML>

```

## *array.join(separatorString)*

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓		✓	✓	✓	✓

### Example

The script in Listing 37-7 converts an array of planet names into a text string. The page provides you with a field to enter the delimiter string of your choice and shows the results in a textarea.

### Listing 37-7: Using the Array.join() Method

```

<HTML>
<HEAD>
<TITLE>Array.join()</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
solarSys = new Array(9)
solarSys[0] = "Mercury"
solarSys[1] = "Venus"
<HTML>
solarSys[2] = "Earth"
solarSys[3] = "Mars"
solarSys[4] = "Jupiter"
solarSys[5] = "Saturn"
solarSys[6] = "Uranus"
solarSys[7] = "Neptune"
solarSys[8] = "Pluto"

// join array elements into a string
function convert(form) {
 var delimiter = form.delim.value
 form.output.value = unescape(solarSys.join(delimiter))
}
</SCRIPT>
<BODY>
<H2>Converting arrays to strings</H2>
This document contains an array of planets in our solar system.<HR>
<FORM>
Enter a string to act as a delimiter between entries:
<INPUT TYPE="text" NAME="delim" VALUE="," SIZE=5><P>
<INPUT TYPE="button" VALUE="Display as String" onClick="convert(this.form)">
<INPUT TYPE="reset">
<TEXTAREA NAME="output" ROWS=4 COLS=40 WRAP="virtual">
</TEXTAREA>
</FORM>
</BODY>
</HTML>

```

Notice that this method takes the parameter very literally. If you want to include nonalphanumeric characters, such as a newline or tab, do so with URL-encoded characters (%0D for a carriage return; %09 for a tab) instead of inline string literals. In Listing 37-7, the results of the `array.join()` method are subjected to the `unescape()` function in order to display them in the `TEXTAREA`.

`array.reverse()`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓		✓	✓	✓	✓

**Example**

Listing 37-8 is an enhanced version of Listing 37-7, which includes another button and function that reverse the array and display it as a string in a text area.

**Listing 37-8: Array.reverse() Method**

```

<HTML>
<HEAD>
<TITLE>Array.reverse()</TITLE>
<SCRIPT LANGUAGE="JavaScript1.1">
solarSys = new Array(9)
solarSys[0] = "Mercury"
solarSys[1] = "Venus"
solarSys[2] = "Earth"
solarSys[3] = "Mars"
solarSys[4] = "Jupiter"
solarSys[5] = "Saturn"
solarSys[6] = "Uranus"
solarSys[7] = "Neptune"
solarSys[8] = "Pluto"

// show array as currently in memory
function showAsIs(form) {
 var delimiter = form.delim.value
 form.output.value = unescape(solarSys.join(delimiter))
}
// reverse array order, then display as string
function reverseIt(form) {
 var delimiter = form.delim.value
 solarSys.reverse() // reverses original array
 form.output.value = unescape(solarSys.join(delimiter))
}
</SCRIPT>
<BODY>
<H2>Reversing array element order</H2>
This document contains an array of planets in our solar system.<HR>
<FORM>

```

*Continued*

**Listing 37-8 (continued)**

```

Enter a string to act as a delimiter between entries:
<INPUT TYPE="text" NAME="delim" VALUE="," SIZE=5><P>
<INPUT TYPE="button" VALUE="Array as-is" onClick="showAsIs(this.form)">
<INPUT TYPE="button" VALUE="Reverse the array" onClick="reverseIt(this.form)">
<INPUT TYPE="reset">
<INPUT TYPE="button" VALUE="Reload" onClick="self.location.reload()">
<TEXTAREA NAME="output" ROWS=4 COLS=60>
</TEXTAREA>
</FORM>
</BODY>
</HTML>

```

Notice that the `solarSys.reverse()` method stands by itself (meaning, nothing captures the returned value) because the method modifies the `solarSys` array. You then run the now inverted `solarSys` array through the `array.join()` method for your text display.

`array.sort([compareFunction])`

	NN2	NN3	NN4	NN6	IE3/J1	IE3/J2	IE4	IE5	IE5.5
<b>Compatibility</b>		✓	✓	✓		✓	✓	✓	✓

**Example**

You can look to Listing 37-9 for a few examples of sorting an array of string values. Four buttons summon different sorting routines, three of which invoke comparison functions. This listing sorts the planet array alphabetically (forward and backward) by the last character of the planet name and also by the length of the planet name. Each comparison function demonstrates different ways of comparing data sent during a sort.

**Listing 37-9: Array.sort() Possibilities**

```

<b>Compatibility</b>			✓	✓					✓

**Example**

Use The Evaluator (Chapter 13) to experiment with the `splice()` method. Begin by creating an array with a sequence of numbers:

```
a = new Array(1,2,3,4,5)
```

Next, remove the center three items, and replace them with one string item:

```
a.splice(1, 3, "two/three/four")
```

The Results box shows a string version of the three-item array returned by the method. To view the current contents of the array, enter `a` into the top text box.

To put the original numbers back into the array, swap the string item with three numeric items:

```
a.splice(1, 1, 2, 3, 4)
```

The method returns the single string, and the `a` array now has five items in it again.

    - constructor, Image object, CD-110–CD-111
    - dummy functions, 50
    - elements, passing to, CD-83–CD-85
    - filter functions, 1152–1156
    - form data, passing to, CD-83–CD-85
    - global, 1128–1136
    - invoking, 1102–1103, CD-29
    - libraries, 1107–1108
    - names, CD-51
    - overloading, 59
    - parameters, CD-51–52
    - parameters, passing, 286–287
    - recursion, 1107
    - validation, combining, 1156–1158
    - values, returning, 59
- ## G
- generic objects
    - event handlers, 192–216
    - methods, 150–191
    - properties, 109–150
  - getAdjacentText() method, 165–166
  - GetAttention() method, 264
  - getAttribute() method, 166–167
    - userProfile object, 709
  - getAttributeNode() method, 167–169
  - getBookmark() method, TextRange object, 462–463
  - getBoundingClientRect() method, 169
  - getClientRects() method, 169–170
  - getElementById() method, document object, 388–389
  - getElementsByName() method, document object, 389
  - getElementsByTagName() method, 170–171
  - getExpression() method, 171
  - getIEVersion() function, 95
  - getSelection() method, document object, 390
  - getters, object property, 1118–1119
  - global functions, 1128–1136
  - global property, regular expression object, 1024
  - global statements, 1137–1146
  - global variables, 1103–1106, CD-53
    - example, CD-53–CD-54
    - host environment and, 58
  - go() method, history object, 336–337
  - goNext() function, CD-105
  - graphics application, 1355–1357
  - Greenwich Mean Time (GMT), 967–969, CD-94

**H**

- handleEvent() method
  - document object, 390
  - FORM element object, 542
  - FORM object, 542
  - window object, 264–265
- hasChildNodes() method, 171–172
- hash property
  - A element object, 499
  - Anchor element object, 499
  - AREA element object, 523–524
  - Link element object, 499
  - location object, 324
- head, scripts in, CD-25
- HEAD element object, 474–475
- headers property
  - TD element object, 654
  - TH element object, 654
- HEIGHT attribute, 124, CD-110
- height property, 124
  - APPLET element object, 905
  - document object, 365
  - EMBED element object, 915
  - FRAME element object, 302
  - Image element object, 513
  - MARQUEE element object, 422
  - OBJECT element object, 911
  - screen object, 699–700
  - TABLE element object, 636
  - TD element object, 655–656
  - TH element object, 655–656
  - TR element object, 650–651
- helpers, 6
- H1..H6 element objects, 414–415
- Hidden Input object, 582–583
- hidden property, EMBED element object, 915
- hide() method, 318–319
- hideFocus property, 125
- hiding scripts, CD-27
- hierarchy
  - containment, 73–74
  - frames, CD-100
  - objects, CD-10–CD-11
- hijacking, cookies, 350
- History object, CD-69
  - methods, 335–337
  - properties, 333–334
- history property, 240
- home() method, 265
- host environment, 57
  - global scope and, 58
- host property
  - A element object, 499
  - Anchor element object, 499
  - AREA element object, 523–524
  - Link element object, 499
  - location object, 325
- hostname property
  - A element object, 499
  - Anchor element object, 499
  - AREA element object, 523–524
  - Link element object, 499
  - location object, 325
- HR element object, 415–418
- href property
  - A element object, 499
  - Anchor element object, 499
  - AREA element object, 523–524
  - BASE element object, 476
  - Link element object, 481–482, 499
  - location object, 326–327
  - styleSheet object, 785
- hrefLang property
  - A element object, 500
  - Anchor element object, 500
  - Link element object, 482, 500
- hspace property
  - APPLET element object, 905–906
  - IFRAME element object, 314
  - Image element object, 513
  - MARQUEE element object, 422
  - OBJECT element object, 911–912
- HTAs (HTML applications), 76
- htc extension, 76
- HTML applications, 76
- HTML collections, 176
- HTML element object, 473–474

- HTML (Hypertext Markup Language), 4–5
    - debugging tags, 1226–1227
    - delimiter characters in tags, 4
    - documents, called by applets, 1196–1197
    - editable content, 118
    - element objects, 71–73
    - forms and, 1313–1319
    - loading to layers, 889–890
    - tags, 4–5
  - htmlFor property
    - LABEL element object, 419, 548
    - SCRIPT element object, 488–489
  - htmlText property, TextRange object, 453–454
  - hybrid tables (dynamic/static), 1293
  - HyperCard, 7
- I**
- ID attribute, 125, CD-15
    - signing scripts, 1249–1250
  - id property, 125
    - styleSheet object, 785
  - identifiers (objects), CD-15
    - id property, 125
  - ids property, document object, 366
  - IE/Windows objects, plug-in detection, 695–698
  - if constructions, CD-48–CD-49
  - if...else constructions, CD-49
  - IFRAME element object, 310–316
    - properties, 311–316
  - ignoreCase property, regular expression object, 1024
  - Image element object, 505–520
    - event handlers, 519–520
    - properties, 509–519
  - Image Input object, 565–567
    - properties, 566–567
  - Image object, 69, CD-109–CD-115
    - constructor function, CD-110–CD-112
    - property values, 124
  - image rollovers, CD-112–CD-115
  - image swapping, 51–52
  - imageOff() function, CD-113
  - imageOn() function, CD-113
  - images
    - basic object model and, 69
    - interchangeable, CD-110
    - precaching, CD-110–CD-112
    - src property, CD-110
  - images property, document object, 366–367
  - <IMG> tag, CD-109
  - immediate scripting, dynamic tables and, 1286
  - immediate statements, CD-28
  - implementation property, document object, 367–368
  - importing style sheets, 779–780
  - imports property, styleSheet object, 785–786
  - indexes, CD-55
    - branching pages, 47–49
  - inheritance
    - containment comparison, 222–223
    - hierarchy, 65
    - prototype-based, 59
    - prototypes, 1121–1123
  - initial expression, loops, CD-50
  - initializing
    - arrays, 988
    - variables, CD-37
  - inline branching, browser compatibility, 1262–1263
  - inline display properties, styles, 812–821
  - innerHeight property, 240–241
  - innerHTML property, 72, 126–127
  - innerText property, 72, 126–127
  - innerWidth property, 240–241
  - input, text input elements, CD-12–CD-13, CD-16
  - Input object, this keyword and, CD-84
  - input property, RegExp object, 1028–1029
  - inRange() method, TextRange object, 463
  - insertAdjacentElement() method, 123, 172–173
  - insertAdjacentHTML() method, 173–175

- insertAdjacentText() method, 173–175
  - insertBefore() method, 86, 175
  - insertCell() method, TR element property, 651–652
  - insertData() method
    - Text object, 447–448
    - TextNode object, 447–448
  - insertNode() method, Range object, 437
  - insertRow() method
    - TABLE element object, 640–641
    - tables, 621–625
  - insertRule() method, styleSheet object, 792
  - installation, plug-ins, 694–695
  - integer numbers, 952–954
    - hexadecimal, 954–955
    - octal, 954–955
  - integers, CD-41
  - intelligent updated flags application, 1365–1373
  - interactive data, CD-5
  - interactivity, CD-2
  - interCap format, naming, CD-38
    - functions, CD-51
  - international characters, signed scripts, 1258
  - Internet Explorer
    - event bubbling, 74–75
    - event object, 745–762
    - event object references, 732
    - extensions, 71–76
    - HTML element features in common, 72
    - JavaScript versions, 37–38
    - objects, 1140
    - open() method, 274
    - printing, 276
    - selection object, 442
    - sticky cursor, 381
    - syntax, NN6 and, 99–102
    - versions, 55
  - invoking functions, 1102–1103, CD-29
  - invoking methods, CD-19
  - isChar property, event object (NN6+), 771
  - isContentEditable property, 127
  - isDisabled property, 127–128
  - isEmpty() function, 1152–1153
  - isEqual() method, TextRange object, 463–464
  - isFinite() function, 1132
  - ISINDEX element object, 478–479
  - isInteger() function, 1154
  - isMap property, Image element object, 514
  - isMultiLine property, 128
  - isNaN() function, 1132–1133
  - isNumber() function, 1155
  - isOpen property, 318
  - isPosInteger() function, 1153–1154
  - isTextEdit property, 128–129
  - isValidFragment() method, Range object, 437–438
  - item() method, 111, 175–176
    - SELECT input object, 606
- ## J
- Java applets, 7
  - JavaScript, 7–10
    - enabling, 44–46
    - JScript comparison, 40
    - reasons to use, 9–10
    - VBScript comparison, 40
    - versions, 37–38
    - when to use, CD-7–CD-8
  - joining strings, CD-90–CD-91
  - js files, 42–43
  - JScript, 9, 14–15, CD-35
    - JavaScript comparison, 40
  - JObject class, 1191–1193
  - jukebox example, 1206–1209
- ## K
- key codes/character codes comparison, 208
  - keyboard
    - accessKey property, 109–110
    - event tasks, 208–210
  - keyCode property, event object
    - IE4, 757–758
    - NN6+, 767–768
  - keywords, reserved, 1447, CD-37

**L**

- LABEL element object, 418–419, 547–548
- label property
  - OPTGROUP element object, 609–610
  - OPTION element object, 608–609
- LANG attribute, 129
- lang property, 129
- language
  - core language, 14–15
  - object-based, 57–58
  - objects and, 13–14
  - scripting languages, 57
  - version selection, 39
- LANGUAGE attribute, 39, CD-23–CD-24
- language property, 129–130
- lastChild property, 123
- lastIndex property, regular expression object, 1024–1025
- lastMatch property, RegExp object, 1029
- lastModified property, document object, 368–369
- lastPage() method, TABLE element object, 641
- lastParen property, RegExp object, 1030
- <LAYER> tag, 71
- layers, 855–856
  - background, 875–877
  - color, 876–877
  - dragging, 894–899
  - forms and, 859–860
  - loading HTML, 889–890
  - methods, 870–873
  - Navigator 4, 70–71
  - nested, 883–889
  - object detection and, 52
  - resizing, 894–899
  - stacking order, 892–894
  - tables and, 617, 860
- layers property, document object, 369–370
- layerX property, event object
  - NN4, 742–743
  - NN6+, 768–769
- layerY property, event object
  - NN4, 742–743
  - NN6+, 768–769
- layout properties, styles, 812–821
- left property
  - layers, 864–865
  - TextRectangle object, 471–472
- leftContext property, RegExp object, 1030
- leftMargin property, BODY element object, 402–403
- length property, 130–131
  - Array object, 996
  - FORM element object, 540
  - FORM object, 540
  - Function object, 1100
  - history object, 334
  - JavaScript versions, 37–38
  - plugin object, 689–690
  - Radio Input object, 562
  - SELECT input object, 599–600
  - string object, 933
  - strings, CD-93
- Level 4 browsers, 14
- LI element object, 660–662
  - examples, 660–662
- libraries
  - compatibility, 43
  - filter functions, 1152–1156
  - functions, 1107–1108
  - script libraries, 42–43, 98
- line terminators, 60
- lineNumber property, Error object, 1065
- Link element object, 480–484, 493–504
  - backward-compatible event handlers, 495–496
  - backward-compatible properties, 495
  - event handlers, 484
  - properties, 481–484, 498–504
- link object, CD-73
- link property, BODY element object, 400–401, 403

- linkColor property, document object, 344–345, 370
  - links property, document object, 370–371
  - list properties
    - currentStyle object, 832–833
    - runtimeStyle object, 832–833
    - style object, 832–833
  - literal notation (arrays), 991
  - LiveConnect, 1177–1178
    - applet classes, 1190–1191
  - LiveScript, change to JavaScript, 8–9
  - loadCached() function, CD-112
  - loading
    - content, new windows, 272–273
    - framesets, forcing, 221–222
  - loading property, 241
  - local variables, 1103–1106, CD-53
    - example, CD-53–CD-54
  - localName property, 131
  - Location object, CD-11, CD-68–CD-69
    - methods, 330–331
    - properties, 324–329
  - location of errors, 1220–1221
  - location property
    - document object, 371–372
    - window object, 242
  - locationbar property, 234–236, 242
  - long descriptions, elements, 303
  - longDesc property
    - FRAME element object, 303
    - IFRAME element object, 314–315
    - Image element object, 514–515
  - lookup tables
    - implementation, 1300–1301
    - serverless databases, 1299–1300
    - source code, 1301–1308
  - lookups, small data lookups, CD-3–CD-4
  - loop property
    - Image element object, 514
    - MARQUEE element object, 422–423
  - loops, CD-47–CD-48
    - for, 1039–1044
    - conditions, CD-50
    - do-while, 1045–1046
    - initial expressions, CD-50
    - interval action, 258
    - for loops, CD-50
    - MARQUEE element object, 422–423
    - nested, labeled statements, 1048–1050
    - object properties, extracting, 1046–1047
    - repeat loops, CD-50
    - update expressions, CD-50
    - while, 1045–1046
  - lowSrc property, Image element object, 515
  - lowsrc property, Image element object, 515
  - Lynx, 49
- ## M
- MacOS, authoring and, 22
  - makeNewWindow() function, CD-64, CD-72
  - MAP element object, 524–525
  - map puzzle application (DHTML), 1399–1414
  - marginHeight property
    - FRAME element object, 303
    - IFRAME element object, 315
  - marginWidth property
    - FRAME element object, 303
    - IFRAME element object, 315
  - MARQUEE element object, 420–423
    - event handlers, 424–425
    - methods, 424
    - properties, 420–423
  - Math object, 957–960, CD-93–CD-94
    - methods, CD-93–CD-94
    - random numbers, 959–960
  - Math.floor() method, CD-94
  - Math.random() method, CD-93–CD-94
  - maximize() method, 66
  - maxLength property, Text Input object, 575
  - media property
    - document object, 372
    - Link element object, 482
    - STYLE element object, 781
    - styleSheet object, 786
  - memory management, 60
  - MENU element object, 663
  - menubar property, 234–236

- mergeAttributes() method, 176–177
- message property, Error object, 1065–1066
- META element object, 484–487
- <META> tag, 49

- TextRange object, 453–454
- TextRectangle object, 471–472
- TH element object, 654–656
- TR element object, 650–651
- value, text-related elements and,
  - CD-78–CD-79
- window object, 229–254
- windows, CD-65–CD-68
  - access, 227
- XML Element object, 921–923
- propertyName property, event object (IE4), 758–759
- proprietary object models, CD-10
- protocol property
  - A element object, 499
  - Anchor element object, 499
  - AREA element object, 523–524
  - document object, 374
  - Image element object, 516–517
  - Link element object, 499
  - location object, 328
- protocolLong property
  - A element object, 501
  - Anchor element object, 501
  - Link element object, 501
- prototype-based inheritance, 59
- prototype properties, read-only, 90–91
- prototype property
  - Array object, 996–998
  - string object, 934–935
- prototypes
  - adding, 1120–1121
  - inheritance, 1121–1123
- public instance variables, 1180

**Q**

- Q element objects, 410
- qualifier property, event object (IE4), 749–750
- queries, CGI scripting and, 5
- queryCommandCommandState() method,
  - document object, 392–393
- queryCommandEnabled() method
  - document object, 392–393
  - TextRange object, 468
- queryCommandIndeterm() method,
  - TextRange object, 468
- queryCommandIndterm() method,
  - document object, 392–393
- queryCommandState() method, TextRange object, 468
- queryCommandSupported() method
  - document object, 392–393
  - TextRange object, 468
- queryCommandText() method
  - document object, 392–393
  - TextRange object, 468
- queryCommandValue() method
  - document object, 392–393
  - TextRange object, 468

**R**

- Radio Input object, 564–565
  - event handlers, 564–565
  - methods, 564
  - properties, 561–564
- radio object, CD-80–CD-81
- random numbers, 959–960
- Range object, 425–441
  - methods, 431–441
  - properties, 429–431
- ranges, creating, 427–429, 450–451
- readOnly property
  - cssRule object, 794
  - rule object, 794
  - styleSheet object, 789
  - Text Input object, 576
- readyState property, 141–142

- real-time validation, 1149–1151
- reason property, event object (IE4), 749–750
- recalc() method, document object, 394
- recordNumber property, 142
- recordset property, event object (IE4), 749–750
- recursion, functions, 1107
- references
  - child/child, CD-102–CD-103
  - child/parent, CD-102
  - event object, 732–734
  - frames, 220
  - function references, 155
  - layers, 858–859
  - objects, CD-14–CD-17
  - parent/child, CD-101–CD-102
  - windows, CD-106–CD-107
- referrer property, document object, 374
- refresh() method
  - plugin object, 690–691
  - TABLE element object, 642–643
- RegExp object, 1027–1031
- regular expression object, 1023–1024
  - methods, 1025–1027
  - properties, 1024–1025
- regular expressions, 1007–1008
  - matches, getting information about, 1019–1020
  - objects, 1013–1017
  - operator precedence, 1012
  - simple, 1009
  - special characters, 1009–1012
  - string replacement, 1021–1022
- rel property
  - A element object, 502
  - Anchor element object, 502
  - Link element object, 482–483, 502
- relatedTarget property, event object (NN6+), 771–772
- releaseCapture() method, 177–179
- releaseEvents() method, 70
  - document object, 394
  - window object, 277–278
- reload() method, location object, 330–331
- reloading, authoring and, 23
- removeAttribute() method, 179–180
- removeAttributeNode() method, 180–181
- removeBehavior() method, 181–182
- removeChild() method, 86, 182
- removeEventListener() method, 151–153
- removeExpression() method, 182–183
- removeNode() method, 183
- repeat loops, CD-50
- repeat property, event object (IE4), 759
- replace() method, location object, 331
- replaceAdjacentText() method, 184
- replaceChild() method, 86, 184–185
- replaceData() method
  - Text object, 447–448
  - TextNode object, 447–448
- replaceNode() method, 185–186
- reserved keywords, 1447, CD-37
- reset() method, FORM element object, 542–543
- resistor example, interactivity, CD-5
- resizeBy() method, window object, 278–279
- resizeTo() method, window object, 278–279
- returnValue property
  - event object (IE4), 759–760
  - window object, 249
- rev property
  - A element object, 502
  - Anchor element object, 502
  - Link element object, 482–483, 502
- right property, TextRectangle object, 471–472
- rightContext property, RegExp object, 1030
- rightMargin property, BODY element object, 402–403
- rollovers, text rollover behaviors, 1280–1283
- routeEvent() method
  - document object, 395
  - window object, 279–280

- rowIndex property, TR element property, 651
- rows, tables, 619–625
- rows property
  - FRAMESET element object, 308
  - TABLE element object, 636–637
  - TEXTAREA element object, 585–586
- rowSpan property
  - TD element object, 655, 656
  - TH element object, 655
- rule object, 792–796
- rules
  - HR element object, 415–418
  - tables, 625–626
- rules property
  - styleSheet object, 789
  - TABLE element object, 637–638
- runtime errors versus syntax errors, 1217–1218
- runtime expressions, debugging scripts and, 1229–1230
- runtimeStyle object, 796–840
  - font properties, 801–812
  - property values, 798–799
  - style properties, 797–798
  - text properties, 801–812
- runtimeStyle property, 142–143

## S

- saveType property, event object (IE4), 760
- scopeName property, 143
- screen object, 698–703
  - examples, 698–703
- screen property, 249–250
- screenLeft property, 250
- screenTop property, 362
- screenX property
  - event object (IE4), 752–754
  - event object (NN4), 742–743
  - event object (NN6+), 768–769
  - window object, 250–251
- screenY property
  - event object (IE4), 752–754
  - event object (NN4), 742–743
  - event object (NN6+), 768–769
  - window object, 250–251
- scrElement property, event object (IE4), 761
- SCRIPT element object, 487–490
- <SCRIPT FOR> tag, 40
- script libraries, 42–43
  - DOM, 98
- script statements
  - behavior components, 1275
  - hiding, 40–41
- <SCRIPT> tag, 25–26, 39–40, CD-23–CD-24
- script1.htm
  - expressions, CD-39
  - source code, 24
- scripting
  - classes, directly, 1214–1215
  - deferred, dynamic tables and, 1286
  - different browsers, 46–53
  - forms and, 1313–1319
  - frames, CD-103
  - immediate, dynamic tables and, 1286
  - jukebox example, 1206–1209
  - language version selection, 39
  - plug-ins, 1197–1214
  - radio objects, CD-81
  - strategies, 16–17
- scripting languages, 57
- scripting methods, 1181–1185
- scripting versus programming, CD-32–CD-33
- scripts, CD-1–CD-2
  - body and, CD-25
  - comment tag, 26
  - debugging (*See* debugging scripts)
  - deferred, CD-28–CD-30
  - embedding in HTML documents, 38–44
  - entering, 23–25
  - errors, 244
  - errors, viewing, CD-30–CD-32
  - event binding, 75
  - head and, CD-25
  - head and body, CD-25–CD-26
  - hiding from older browsers, CD-27

*Continued*

- scripts (*continued*)
  - intermittent working, 1227–1228
  - multiple-level, 49–50
  - onLoad event handler and, CD-29
  - privileges, 1254
  - signing, security, 1247–1251
  - user actions and, CD-30
- scripts property, document object, 375
- scroll() method, 280–281
- scroll property, BODY element object, 404
- scrollAmount property, MARQUEE element object, 423
- scrollbar properties
  - currentStyle object, 834
  - runtimeStyle object, 834
  - style object, 834
- scrollbars property, 251
- scrollBy() method, 281–282
- scrollDelay property, MARQUEE element object, 423
- scrollHeight property, 144
- scrolling
  - coordinates and, 280–281
  - mouse scroll button, 282
- scrolling property
  - FRAME element object, 304
  - IFRAME element object, 315
- scrollIntoView() method, 186
- scrollLeft property, 144–145
  - BODY element object, 404
- scrollTo() method, window object, 281–282
- scrollTop property, 144–145
  - BODY element object, 404
- scrollWidth property, 144
- scrollx property, 251
- scrolly property, 251
- search property
  - A element object, 499
  - Anchor element object, 499
  - AREA element object, 524
  - Link element object, 499
  - location object, 328–329
- searches, strings, CD-91–CD-92
- sectionRowIndex property, TR element property, 651
- SECURE parameter, cookies, 352
- security, 1239–1241
  - digital certificates, 1246–1247
  - Netscape signed script policy, 1244–1245
  - origin checks, 1243–1244
  - policies, 1241–1242
  - Privilege Manager errors, 1255–1256
  - same origin policy, 1242–1244
- security property, document object, 375
- SELECT input object, 592–599
- select() method
  - Text Input object, 579–580
  - TextRange object, 469
- SELECT element object, 589–607
  - event handlers, 606–607
  - methods, 605–606
  - properties, 599–605
- SELECT form control, CD-77
  - images, CD-112
- SELECT object, CD-82–CD-83
  - navigating with, CD-82
- <SELECT> tag, 591
- selectedIndex property, SELECT input object, 603–604
- selection lists, 589
- selection object, 441–445
  - methods, 443–445
  - properties, 443
- selection property, document object, 376
- selectNode() method, Range object, 438–439
- selectNodeContents() method, Range object, 438–439
- selectorText property
  - cssRule object, 794–795
  - rule object, 794–795
- self property, 228, 252
- self.close() method, CD-64
- serverless databases, lookup tables and, 1299–1300
- servers, offloading busy, CD-8

- servlets, 7
- setActive() method, 186–187
- setAttribute() method, 87, 187–188
- setAttributeNode() method, 188
- setCapture() method, 177–179, 188
- setCursor() method, 282–283
- setEnd() method, Range object, 439–440
- setEndAfter() method, Range object, 440
- setEndBefore() method, Range object, 440
- setEndPoint() method, TextRange object, 469–470
- setExpression() method, 188–190
- setInterval() method, 258, 283–285
- setStart() method, Range object, 439–440
- setStartAfter() method, Range object, 440
- setStartBefore() method, Range object, 440
- setters, object property, 1118–1119
- setTimeout() method, 285–287
- SGML (Standard Generalized Markup Language), 4
- shape property
  - A element object, 498–499
  - Anchor element object, 498–499
  - AREA element object, 523
  - Link element object, 498–499
- shiftKey property
  - event object (IE4), 747–748
  - event object (NN6+), 764–765
- shiftLeft property, event object (IE4), 748–749
- show() method, 318–319
- showHelp() method, 287
- showModalDialog() method, 233, 288–291
- showModelessDialog() method, 233, 288–291
- sibling elements, 132
- siblingAbove property, layers, 860–864, 897–868
- siblingBelow property, layers, 860–861, 897
- sidebar property, 229, 252
- signed scripts, 1244–1245, 1247–1251
  - exporting/importing, 1257
- SignTool, scripts and, 1247–1248
- simple regular expressions, 1009
- size property
  - BASEFONT element object, 478
  - FONT element object, 413–414
  - HR element object, 416, 417
  - SELECT input object, 604
  - Text Input object, 576–577
- sizeToContent() method, 291
- small data lookups, CD-3–CD-4
- sniffers, browser sniffer script, 48
- sound, embedding multiple, 1209–1214
- source code
  - calculations application, 1357–1363
  - decision helper application, 1378–1397
  - frames, viewing, 224
  - graphics application, 1357–1363
  - lookup tables, 1301–1308
  - script1.htm, 24
  - table of contents, outline style, 1324–1336
- source property, regular expression object, 1025
- sourceIndex property, 145
- space characters, variable names, CD-38
- span property, COL element object, 647–648
- special characters
  - regular expressions, 1009–1012
  - strings, 929–926
- splitText() method
  - Text object, 448
  - TextNode object, 448
- square brackets, optional items in loops, CD-50, CD-70
- SRC attribute, CD-24
  - <SCRIPT> tag, 42–43

# Hungry Minds, Inc.

## End-User License Agreement

**READ THIS.** You should carefully read these terms and conditions before opening the software packet(s) included with this book (“Book”). This is a license agreement (“Agreement”) between you and Hungry Minds, Inc. (“HMI”). By opening the accompanying software packet(s), you acknowledge that you have read and accept the following terms and conditions. If you do not agree and do not want to be bound by such terms and conditions, promptly return the Book and the unopened software packet(s) to the place you obtained them for a full refund.

- 1. License Grant.** HMI grants to you (either an individual or entity) a nonexclusive license to use one copy of the enclosed software program(s) (collectively, the “Software”) solely for your own personal or business purposes on a single computer (whether a standard computer or a workstation component of a multi-user network). The Software is in use on a computer when it is loaded into temporary memory (RAM) or installed into permanent memory (hard disk, CD-ROM, or other storage device). HMI reserves all rights not expressly granted herein.
- 2. Ownership.** HMI is the owner of all right, title, and interest, including copyright, in and to the compilation of the Software recorded on the disk(s) or CD-ROM (“Software Media”). Copyright to the individual programs recorded on the Software Media is owned by the author or other authorized copyright owner of each program. Ownership of the Software and all proprietary rights relating thereto remain with HMI and its licensors.
- 3. Restrictions On Use and Transfer.**
  - (a)** You may only (i) make one copy of the Software for backup or archival purposes, or (ii) transfer the Software to a single hard disk, provided that you keep the original for backup or archival purposes. You may not (i) rent or lease the Software, (ii) copy or reproduce the Software through a LAN or other network system or through any computer subscriber system or bulletin-board system, or (iii) modify, adapt, or create derivative works based on the Software.
  - (b)** You may not reverse engineer, decompile, or disassemble the Software. You may transfer the Software and user documentation on a permanent basis, provided that the transferee agrees to accept the terms and conditions of this Agreement and you retain no copies. If the Software is an update or has been updated, any transfer must include the most recent update and all prior versions.

**4. Restrictions on Use of Individual Programs.** You must follow the individual requirements and restrictions detailed for each individual program in Appendix E of this Book. These limitations are also contained in the individual license agreements recorded on the Software Media. These limitations may include a requirement that after using the program for a specified period of time, the user must pay a registration fee or discontinue use. By opening the Software packet(s), you will be agreeing to abide by the licenses and restrictions for these individual programs that are detailed in Appendix E and on the Software Media. None of the material on this Software Media or listed in this Book may ever be redistributed, in original or modified form, for commercial purposes.

**5. Limited Warranty.**

- (a) HMI warrants that the Software and Software Media are free from defects in materials and workmanship under normal use for a period of sixty (60) days from the date of purchase of this Book. If HMI receives notification within the warranty period of defects in materials or workmanship, HMI will replace the defective Software Media.
- (b) **HMI AND THE AUTHOR OF THE BOOK DISCLAIM ALL OTHER WARRANTIES, EXPRESS OR IMPLIED, INCLUDING WITHOUT LIMITATION IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE, WITH RESPECT TO THE SOFTWARE, THE PROGRAMS, THE SOURCE CODE CONTAINED THEREIN, AND/OR THE TECHNIQUES DESCRIBED IN THIS BOOK. HMI DOES NOT WARRANT THAT THE FUNCTIONS CONTAINED IN THE SOFTWARE WILL MEET YOUR REQUIREMENTS OR THAT THE OPERATION OF THE SOFTWARE WILL BE ERROR FREE.**
- (c) This limited warranty gives you specific legal rights, and you may have other rights that vary from jurisdiction to jurisdiction.

**6. Remedies.**

- (a) HMI's entire liability and your exclusive remedy for defects in materials and workmanship shall be limited to replacement of the Software Media, which may be returned to HMI with a copy of your receipt at the following address: Software Media Fulfillment Department, Attn.: *JavaScript Bible, Gold Edition*, Hungry Minds, Inc., 10475 Crosspoint Blvd., Indianapolis, IN 46256, or call 1-800-762-2974. Please allow four to six weeks for delivery. This Limited Warranty is void if failure of the Software Media has resulted from accident, abuse, or misapplication. Any replacement Software Media will be warranted for the remainder of the original warranty period or thirty (30) days, whichever is longer.

- (b) In no event shall HMI or the author be liable for any damages whatsoever (including without limitation damages for loss of business profits, business interruption, loss of business information, or any other pecuniary loss) arising from the use of or inability to use the Book or the Software, even if HMI has been advised of the possibility of such damages.
- (c) Because some jurisdictions do not allow the exclusion or limitation of liability for consequential or incidental damages, the above limitation or exclusion may not apply to you.

**7. U.S. Government Restricted Rights.** Use, duplication, or disclosure of the Software for or on behalf of the United States of America, its agencies and/or instrumentalities (the "U.S. Government") is subject to restrictions as stated in paragraph (c)(1)(ii) of the Rights in Technical Data and Computer Software clause of DFARS 252.227-7013, or subparagraphs (c) (1) and (2) of the Commercial Computer Software - Restricted Rights clause at FAR 52.227-19, and in similar clauses in the NASA FAR supplement, as applicable.

**8. General.** This Agreement constitutes the entire understanding of the parties and revokes and supersedes all prior agreements, oral or written, between them and may not be modified or amended except in a writing signed by both parties hereto that specifically refers to this Agreement. This Agreement shall take precedence over any other documents that may be in conflict herewith. If any one or more provisions contained in this Agreement are held by any court or tribunal to be invalid, illegal, or otherwise unenforceable, each and every other provision shall remain in full force and effect.

## CD-ROM Installation Instructions

The files on this CD-ROM can be accessed and used from both Windows 95 (or later) and Macintosh environments. Some Macintosh program files require MacOS 8.6 or later, but program listing text files can be opened with any MacOS version. For Windows, access the software with My Computer or Windows Explorer. Macintosh users can access files by using the Finder.

You can open all of the example file listings directly from the CD-ROM, but access will be faster — and you will be able to experiment with modifying the files more readily — if you copy the listings to your hard drive. Copy the folder named Listings from the CD-ROM to any location on your hard drive.

To open the listing scripts on this CD-ROM, you should have a copy of Microsoft Internet Explorer 5 (or later), Netscape Navigator 6 (or later), or both browsers installed on your computer. You will find installers for recommended minimum versions of the two browsers on this CD-ROM.

To run the listing scripts from your browser, open the file named index.html in the Listings folder. This page provides a table of contents consisting of direct links to the listings, showing which browsers are compatible with each listing.

Access the Adobe Acrobat (PDF) files for the book's contents from the CD-ROM. Be sure to install the index files into your copy of Acrobat to take advantage of full-text search.

For more details on installing and running the CD-ROM contents, see Appendix E.
